Introduction

About ADE

This chapter provides an overview of the Analytica Decision Engine (ADE) and summarizes the information presented in this book.
What is the Analytica Decision Engine?

The *Analytica Decision Engine* (ADE) is a powerful COM component that helps you to access Analytica models via a program. ADE lets you run any Analytica model on a server computer. It provides an Application Programming Interface (API) through which other application programs can create, read, check, parse, evaluate, modify, and save Analytica models. For example, you can create a user interface accessible via a web browser so that users can run Analytica models as web applications. Or you can use ADE to access your Analytica model from another application that can supply inputs, run the model, and collect and display results.

Although you can use ADE to build and edit models with commands issued via the API, it is usually much more convenient to use Analytica Enterprise for this purpose (see the *Analytica Tutorial* and *Analytica User Guide* for details, including the “Analytica Enterprise” chapter of the *Analytica User Guide*). After you have an Analytica model, you can use ADE to build a custom user interface via a web browser or other application, to interface the model with another application.

ADE is provided in two forms so that it is compatible with a wide range of applications. These forms are an ActiveX in-process automation server, `Adew.dll`, and a COM local automation server, `ADE.exe`. The classes, methods, and properties exposed by these servers are accessible from any programming environment that supports the use of COM, ActiveX Automation, or .NET interfaces. Such environments include VB, VB.NET, ASP, ASP.NET, C#, Visual C/C++, J#, VB Script, and JavaScript. For example, you can use Visual Basic or C# to create graphical user interfaces (GUIs) on 32-bit Microsoft Windows platforms for your Analytica models, tailored to specific applications and specific classes of end users.

Figure shows a conceptual model of ADE. Your application makes calls to the functions exposed by the interface classes of ADE. Those functions then return information to your application. Server objects allow you to read, check, parse, evaluate, modify, and save Analytica models from within your applications.

Using the ADE server

ADE provides objects of six OLE classes: `CALicense`, `CAEngine`, `CAObject`, `CATable`, `CIndex`, and `CARenderingStyle` ("CA" stands for Class Analytica). You use these classes to interact with your Analytica model through ADE. The `CAEngine` class contains methods and properties to open and close existing models, create new models, and access objects in your Analytica model.

It is important to distinguish these OLE object classes in ADE from the Analytica object classes. Analytica classes include chance, decision, index, objective, and variable (which we refer to collectively as *variable classes*); model, module, and library (which we refer to collectively as *module classes*); functions, and attributes. You can access Analytica objects as instances of the
**Introduction**

**CAObject** class. This class provides properties and methods to get and set attributes of Analytica objects, including identifier, title, and description, as well as definition and value for variables.

You can access the value of a variable via the **ResultTable** property of class **CATable**. A **CATable** represents an Analytica array (also known as a **table**) so that you can get or set its individual elements (also known as **cells**). Each element can be a **number** or a **string** value (termed a **text** value in Analytica).

A **CATable** has zero or more dimensions. Zero dimensions means it is **atomic** (it has a single element). Each dimension is identified by an Analytica index, represented by the **CAIndex** class. A **CAIndex** has a name and a list of labels, numbers, or strings used to identify the rows or columns (more generally, **slices**) of the array. In Analytica, you identify dimensions of an array by name, not by order.

The **CARenderingStyle** class provides control over formatting of returned values as numbers or text.

Before your code can interact with ADE, you must create a **CAEngine** object, from which all else is obtained. You can create a **CAEngine** class directly, or you can first obtain a **CALicense** object, and then use it to create a **CAEngine**. The **CALicense** class can tell you whether your ADE license allows you to create a **CAEngine**, and provide more detailed information about why the **CAEngine** could not be created when a failure occurs.

**How to use this document**

The rest of this guide includes these sections:

**Chapter 1, Installation**

This chapter explains the steps required to install the Analytica Decision Engine 4.6 on your Windows NT 4 (>SP 6), 2000, XP, or Vista computer.

**Chapter 2, The Analytica Decision Engine Tutorial**

This chapter shows you how to use the Analytica Decision Engine (ADE) from within a Visual Basic program, and steps you through building your first ADE application using Visual Basic.

**Chapter 3, Using the Analytica Decision Engine Server**

This chapter provides a step-by-step guide to the functionality accessible through ADE. You should read this section to get better acquainted with the classes, and their methods and properties. By using the sample code fragments presented in this section in your code, you can begin accessing information in your models from your Visual Basic applications immediately.

**Chapter 4, Working with Models, Modules, and Files**

This chapter contains examples of common operations and manipulations you might perform on objects in your Analytica model.

**Chapter 5, ADE Server Class Reference**

This chapter provides reference materials on the six object classes in ADE and their properties and methods, including method syntax, data types, and property access information. Refer to the information in this section after you’ve read through “Chapter 3, “Using the Analytica Decision Engine Server,” and have specific questions about particular methods and properties.
This chapter explains the system requirements for the Analytica Decision Engine (ADE) and describes how to install, upgrade, and uninstall ADE.
System requirements

- 40 MB of hard drive space (you need more space to develop your applications)
- 2GB of RAM.
- You also need a development language environment to build your application using ADE. This could be Visual Studio with VB.NET, C#, ASP.NET, VC++, or any other COM or .NET-enabled development environment. You can also use ADE from Microsoft Office Visual Basic for Applications (VBA) or from Windows Scripting Host (CScript.exe or WScript.exe), as well as other COM-enabled or ActiveX automation-enabled packages.

You can obtain all the files for installation of ADE from the ADE CD-ROM or you can download the installer from http://www.lumina.com/ana/support/download.htm.

The installation contains the ADE in-process automation server (Adew.dll), the ADE local automation server (ADE.exe), auxiliary files needed by ADE, this ADE User Guide, and example programs.

Installing the Analytica Decision Engine files

Installing from the network

Obtain an ADE 4.6 activation key from Lumina. This is supplied to you, usually through e-mail, when you purchase ADE.

Download the ADE setup executable. The location of the file on the internet is provided when you receive your activation key. Save the file to disk.

Run (i.e., double click) the file you just downloaded to begin the ADE installer. Make sure you are running it from an admin account.

Follow the instructions. Read and agree to the license agreement, select a directory for the installation, and enter your activation key when prompted. The installer communicates with Lumina’s activation server to activate and download a license that is keyed to your computer.

The activation process stores a license in a file named ADE.lic. This license is keyed to the computer (the same ADE.lic won’t work on a different computer), but is valid for all users of the same computer, including special accounts used by your web server.

Manual activation

If activation fails as a result of the installer being unable to communicate with the activation server (either because your computer is not connected to the internet, or because your corporate firewall blocked the communication), you will need to manually activate the license. This involves these steps:

1. Allow the installer to finish (leave the activation key blank).
2. Find your computer’s host id as follows.
   a. Start > All Programs > Analytica Decision Engine > Configure License
   b. Find your host id at the bottom right corner of the dialog.
3. Go to http://Lumina.com/support/activate-analytica
4. Select ADE, Individual license, and fill in the remaining fields (make sure your host id is entered exactly, including any hyphens if any) and submit.
5. On the thank you web page, find your license name. It will appear after “LICENSE lumina” and will look something like ade_123_45 (the numbers will differ).
6. When you receive the email, save the attachment (ADE.lic) to the ADE install directory.
7. Run ADE.exe
8. In the dialog that appears, enter your license name from step 5. Leave the RLM Server field blank.
9. Test the installation by running AdeTest and pressing the New ADE.CAEngine button. If this succeeds without reporting a licensing error, you got it right.
Installed Manuals and Examples

The default installation directory, if you did not change it when running the installer, is

C:\Program Files\Lumina\ADE 4.6

Two ADE manuals are installed into a subdirectory called docs. These are:

• ADE Reference.pdf (this document)
• ADE Scripting.pdf

Four example programs should also have been installed in that directory underneath the examples directory. They are as follows:

Tutorial.NET — This program is referred to by the Analytica Decision Engine Tutorial. It is recommended that you read the Analytica Decision Engine Tutorial completely before writing your own programs that depend on ADE.

AdeTest — This program allows you to call or test the methods of ADE objects through a GUI. You can run AdeTest.Exe (in the bin directory), or you can trace through the code in the Visual Studio.NET 2005 debugger to observe each method being called.

asp_exam — This program shows you how to access ADE through a Microsoft ASP program.

eexcel_exam — This program shows you how to access ADE from any application with Visual Basic for Applications (VBA) support, including the Microsoft Office suite of applications.

Entering a new license code

If you need to activate a different license you must run the ADE installer (or go through the manual activation process on page 6).

Upgrading from an earlier version of ADE

ADE 4.6 has been configured to install without disturbing previously installed versions of ADE. This allows you to compare the performance and output of your application under the different versions. However, it also means that your existing applications continue to use the previous version until you have changed them to use ADE 4.6.

Uninstalling ADE

To uninstall ADE, select Add/Remove Programs in the Windows Control Panel. Scroll through the list to find “Analytica Decision Engine 4.6.” Click the Remove button and proceed through the uninstall wizard.
Chapter 2

The Analytica Decision Engine Tutorial

This tutorial shows you how to use the Analytica Decision Engine (ADE) from within a Visual Basic program.
Your first ADE application

First let's write a simple ADE application from scratch, just to be sure that everything is set up correctly. Follow these steps:

1. Bring up Visual Studio.NET.
2. Select **New Project**, then select the Project Type “Visual Basic Projects” and the template “Console Application.” Select a project name, e.g., “FirstADETry,” and an appropriate folder location.
3. From the **Project** menu, select **Add Reference** and select the **COM** tab in the dialog. Find and select **Analytica Decision Engine Local Server 4.6 (ade.exe)** and click **OK**.

**Note:** If you have installed ADE 64-bit and do not have ADE 32-bit installed, Visual Studio may not show **Analytica Decision Engine Local Server 4.6**, even though it is properly installed. This occurs because Visual Studio itself is a 32-bit application. If this happens, select the **Browse** tab on the **Add Reference** dialog, navigate to the ADE install directory (usually `C:\Program Files\Lumina\ADE 4.6`), and select **ADE64.exe**.

**Note:** If you cannot find this entry in the list of COM servers, then ADE 4.6 is not properly installed. See “Installation” on page 5 for instructions on how to install ADE before reading further.

4. Add to the **Module1** class as follows:
   ```vbnet
   Imports ADE
   Module Module1
       Public ADE As CAEngine
       Sub Main()
           Dim FileName, ModelName As String
           FileName = "C:\Program Files\Lumina\Analytica 4.6" & "\Example Models\Tutorial Models\Car Cost.ana"
           ADE = New CAEngine
           ModelName = ADE.OpenModel(FileName)
           If ModelName = "" Then
               Console.Write(FileName & " not found")
           Else
               Console.Write("Congratulations on opening ")
               Console.WriteLine(ModelName)
               Console.WriteLine("Press 'enter' to exit")
               Console.ReadLine()
           End If
       End Sub
   End Module
   
   5. Now run the program. If your program prints “Congratulations on opening Carcosts” you have just successfully written your first ADE program.

This first program did the following:

- Created a **CAEngine** automation object called **ADE** (using `new CAEngine`).
- Opened an Analytica model (using the **OpenModel** method of **CAEngine**).
- Displayed the name of the model (the return value of **OpenModel**).

We go into the details of these and other functions in the next section.
What's next?

We will not attempt to explain all of the features of ADE in this tutorial. These are described in the following chapters of this guide. Here, we give you the background to explore the more advanced features of ADE on your own.

From this point, we use the example model called Txc.ana. You can find Txc.ana in the Risk Analysis folder under the Example Models folder installed with Analytica. If you cannot find it, or if you opted not to install the examples when you originally installed Analytica, there is a copy in the Examples\Tutorial.NET folder in the directory where you installed ADE.

The Txc model demonstrates risk-benefit analysis of reducing the emissions of the fictitious air pollutant TXC. Please open the Txc model with Analytica to see how it works.

The example Visual Basic.NET program called TestTxc in your Ade Examples\Tutorial.NET folder shows many aspects of ADE. This program creates an ADE automation object, opens the Txc.ana model with this object, gets the definition of the Population Exposed variable, evaluates the Total Cost variable, prints out the result of the Total cost variable as a table by getting at the individual components of the table, and changes the definition of the Population Exposed variable. It then gets the result of the Total cost variable again, to see what effect the change of definition for Population Exposed had on the Total Cost variable. If things are set up properly, TestTxc displays the window shown in “Text Txc window”.

The application displays the definition of the Population Exposed variable (“Normal (30M, 3M)”), and the table associated with Total Cost, based on the definition of Population Exposed. You can change the definition of Population Exposed by selecting File > Change Population Exposed from the main menu and seeing the effect this has on the Total Cost table.

Text Txc window

Distinguishing title from identifier

Whenever an ADE function requires a variable, you must pass it the identifier of the variable, not its title. This can be confusing since Analytica normally displays the titles of each variable in an influence diagram. By default, when you first create each object, Analytica automatically creates an identifier based on the title. It substitutes an underscore (_) for each blank or other character in the title that is not a letter or number.
You can show the identifiers in an influence diagram by pressing Control+y (or by selecting **Show by identifier** from the **Object** menu). For model `Txc.ana`, you can see that the identifier of the variable titled `Population Exposed` is `Pop_exp`. It is important to use `Pop_exp` as the identifier when passing this variable to ADE functions. ADE would not be able to find the variable if you pass `Population Exposed` instead, and would return an error.

**Creating an ADE object from within Visual Basic**

If you haven’t already, load the project called `Examples\Tutorial\TestTxc.sln` into Visual Basic.NET, and view the code for the file called `TestTxc.vb`. The code looks like this:

```vbnet
Imports ADEW

Public adeEngine As CAEngine

Public Sub Main()
    Dim exeDirectory, theModel As String
    Dim theModelString As String
    exeDirectory = VB6.GetPath
    theModel = exeDirectory & "\..\" & "Txc.ana"
    adeEngine = New CAEngine
    ...
    theModelString = adeEngine.OpenModel(theModel)
    ...
    frmMain.DefInstance.Show()
End Sub
```

At the very top of the file, the code declares the automation object `adeEngine` as a `CAEngine` object. Using this object, we can access all of the public functions exposed by `CAEngine` (see “ADE Server Class Reference” on page 51 for a complete listing). This line then creates the `CAEngine` object.

```vbnet
    adeEngine = New CAEngine
```

The `adeEngine` variable now holds our in-process `CAEngine` object.

If we want to use the local (out-of-process) server version of ADE, we can add a reference to the project to the `Analytica Decision Engine Server 4.6 COM` component and change the top line from `Imports ADEW` to `Imports ADE`.

Here is another way to obtain a new `CAEngine` object. This sequence does not require adding a reference to the project.

```vbnet
    adeEngine = CreateObject("ADEW4.6.CAEngine") ' in-process
    adeEngine = CreateObject("ADE4.6.CAEngine") ' out-of-process
```

To understand the pros and cons of using an in-process server versus an out-of-process (or local) server, and which automation server to use for different scenarios, see “In-process vs. out-of-process” on page 22, as well as other books related to COM servers.

**COM vs. Automation interface**

In the example above, we used a COM interface to call ADE. In a COM interface, the object (`CAEngine` in this case) is declared as `CAEngine`, and the compiler resolves each member function and can detect several obvious errors at compile time. In addition, Visual Studio can provide a list of methods and parameter types as tool tips as you program, which is helpful when writing programs that use ADE. COM calls are slightly faster than Automation calls, but the speed difference is not usually significant in applications of ADE. With ADE 4.6, we recommend using the COM interface if your programming language supports it.

In VB Automation, you can declare an object simply as `Object`, rather than a more specific types such as `CAEngine`, `CAObject`, and so on. When ADE methods are called using Automation, the
methods are resolved at run time. At compile time, the compiler does not know whether your ADE object has a function named `OpenModel`. In VB, the syntax for calling a COM method or an Automation method is identical — the only difference is whether the object’s type is declared explicitly.

In VC++ and C#, the syntax for calling COM is not the same as for Automation. In these cases, COM is much more convenient, while Automation can get rather tedious. However, some languages, including VBScript and other scripting languages, support only Automation and not COM.

**Monitoring the Process**

When using the out-of-process ADE server, your own code must release the `CAEngine` COM object when it terminates. When this final `CAEngine` usage is released, the ADE.exe process automatically terminates. In the code seen so far, the VB language takes care releasing the object automatically when it reaches the end of the program. However, while you are debugging your own code, you may terminate your program prematurely to fix a bug, your program may be killed from Task Manager, or your own code may crash, causing your program’s process to terminate before it had a chance to release the object. Because the COM object is never released, the ADE.exe process cannot know that it is no longer in use, and you may get zombie ADE.exe processes lingering.

To avoid this, it is a good practice to call `CAEngine::MonitorProcess( .. )` immediately after obtaining a `CAEngine` instance. You pass the method the process id for your program’s own process. In this fashion, ADE can learn which process is using it, and will set up a thread to detect if your process terminates before ADE is fully released. If your program’s process does terminate, the ADE process immediately shuts itself down, eliminating the build-up of zombie ADE processes.

To obtain your process ID from a .NET application, use the `GetCurrentProcess().Id` found in the `System.Diagnostics.Process` namespace. In other languages, you can use the Windows SDK function `GetProcessId( )`.

`MonitorProcess( )` can only be used to monitor processes running on the same computer as ADE’s process, so you can’t use this if running ADE through DCOM. There is no need to use this when using the in-process ADEW server.

**Opening a model with ADE**

We will now open the `Txc.ana` model, and show the main window of our application. Use the following call:

```vbnet
theModelString = adeEngine.OpenModel(theModel)
frmMain.DefInstance.Show
```

The `OpenModel` function of `CAEngine` opens the model. If successful, the variable `theModelString` contains the name of the model. Otherwise, it contains an empty string. Although we haven’t done so in this example for the sake of brevity, you should check to see that the string returned from `OpenModel` isn’t empty. If it is, there was an error in opening your model. You can find out what kind of error with the `ErrorCode` and `ErrorText` properties of `CAEngine` (`adeEngine.ErrorCode` and `adeEngine.ErrorText`). We will see how to use these two properties later on. For a listing of all the error codes, see Appendix A, “Error Codes” on page 74.

**Retrieving objects from the Analytica model**

The next step is to retrieve objects (variables, modules, functions, etc.) from our model, so that we can access their attributes (definition, title, class, etc.). Our example model (`Txc.ana`) manipulates the `Pop_exp` and `Cost` objects. In particular, it modifies `Pop_exp` to see how this effects the `Cost` object.
The **PrintAttributes** function in the file `frmMain.frm` of our `TxcTest.vbproj` (TxcText.sln) project shows how to do this. This function is first called by the `Form_Load` function of `frmMain.frm`, when the application starts, to display the **Cost** table. It is also called whenever we wish to print out the current result of our **Cost** table. The function looks like this:

```vb
Public Sub PrintAttributes(ByRef inputIdentifier As String, ByRef outputIdentifier As String)
    Dim inputObject, outputObject As CAObject
    Dim resultTable As CATable
    Dim definitionAttrInput As String
    inputObject = adeEngine.GetObjectByName(inputIdentifier)
    outputObject = adeEngine.GetObjectByName(outputIdentifier)
    definitionAttrInput = inputObject.GetAttribute("definition")
    resultTable = outputObject.ResultTable
    Call PrintResultTable(resultTable, inputIdentifier,
        definitionAttrInput, outputIdentifier)
    ReleaseComObject(resultTable)
    ReleaseComObject(inputObject)
    ReleaseComObject(outputObject)
End Sub
```

**PrintAttributes** works with the variable identifiers `Pop_exp` passed as parameter `inputIdentifier` and `Cost` passed as parameter `outputIdentifier`. It fetches the corresponding objects using the `GetObjectByName` function of `CAEngine` as follows:

```vb
inputObject = adeEngine.GetObjectByName(inputIdentifier)
outputObject = adeEngine.GetObjectByName(outputIdentifier)
```

If `GetObjectByName` succeeds, it returns an object of type `CAObject`. You then use the functions of `CAObject`. See "SendCommand(command)" on page 56 for a listing all `CAObject` functions. If `GetObjectByName` fails, the return value is `Nothing`. The code should check to make sure that the result from `GetObjectByName` is valid. If not, use the `ErrorCode` and `ErrorText` properties of `CAEngine` to get more information about the error. For example:

```vb
Set inputObject = adeEngine.GetObjectByName(inputIdentifier)
If inputObject Is Nothing Then
    MsgBox("This error from GetObjectByName occurred: ",
        vbCrLf & adeEngine.errorCode & ":" & adeEngine.errorText)
Else
    'inputObject valid
End If
```

### Getting object attributes

Each Analytica object has a set of attributes (analogous to properties), such as identifier, title, description, and class. You can use the `GetAttribute` function to obtain an attribute from an Analytica object. For example, to get the definition of `inputObject` (currently, the cost):

```vb
definitionAttrInput = inputObject.GetAttribute("definition")
```

In the `Txc.ana` model, the definition of `Pop_exp` is "Normal (30M, 3M)" which we store in `definitionAttrInput`.

### Evaluating objects and retrieving results

Use `Result` or `ResultTable` methods of `CAObject` to get the value of a variable. ADE automatically evaluates the variable first, if necessary. Use the `Result` method if you are sure the result will be **atomic**, i.e., a single element. Otherwise, use `ResultTable`, which retrieves the result as an
array. An atomic result is treated as a special case of an array, one with zero dimensions. If the value is atomic, the method \texttt{AtomicValue} returns its single value as a number or string.

By default, \texttt{Result} and \texttt{ResultTable} return the mid value of the result, i.e., the result of ADE evaluating it as deterministic. For a probabilistic value, set the \texttt{ResultType} property of \texttt{CAObject} to the desired uncertainty view — Mean, Sample, PDF, CDF, Confidence bands, or Statistics (see “ResultType” on page 61 for details). We get the value of \texttt{outputObject} like this:

\begin{verbatim}
resultTable = outputObject.ResultTable
\end{verbatim}

The result is a \texttt{CATable} object, which lets us access individual elements in a table.

If you call \texttt{Result} to get an array (or table) value, it returns the array as a string, listing the indexes and elements separated by commas. It is usually easier to use \texttt{ResultTable}, so that you don’t have to parse elements of the table from the string.

### Getting the index elements of a table

An Analytica table has zero or more indexes. If it has one index, then it is one-dimensional; if it has two indexes, it is two-dimensional, and so on. A zero-dimensional table holds a single atomic (or scalar) value. You can use the \texttt{NumDims} function of \texttt{CATable} to get the number of dimensions (same as number of indexes) of a table. To get at the individual indexes of a table, use methods \texttt{IndexNames} and \texttt{GetIndexObject} of \texttt{CATable}.

The function \texttt{PrintResultTable} in \texttt{frmMain.frm} shows the use of these two functions. \texttt{PrintResultTable} is called from \texttt{PrintAttributes}, and does the actual work of printing the table that shows up in our \texttt{TestTxc} application (for brevity, we show only the parts of this function related to ADE).

\begin{verbatim}
Public Sub PrintResultTable(ByRef resultTable As CATable, ByRef inputIdentifier As String, ByRef definitionAttrInput As String, ByRef outputIdentifier As String)
    Dim theIndexName, theTableName As String
    Dim theIndexElement As String
    Dim theTableElement
    Dim theIndexObj As CAIndex
    Dim numEls As Integer
    Dim spaces, i As Integer
    Dim lenStr As Short
    Dim OutputStr As Short
    Dim spaceString, underlineString As String
    ...
    theIndexName = resultTable.IndexNames(1)
    theTableName = resultTable.Name
    theIndexObj = resultTable.GetIndexObject(theIndexName)
    numEls = theIndexObj.IndexElements
    ...
    For i = 1 To numEls
        theIndexElement = theIndexObj.GetValueByNumber(i)
        theTableElement = resultTable.GetDataByElements(i)
        ...
    Next i
    InformationPane.Text = outputString
End Sub
\end{verbatim}

The lines of \texttt{PrintResultTable} that get an index of a table are as follows:

\begin{verbatim}
theIndexName = resultTable.IndexNames(1)
\end{verbatim}
theIndexObj = resultTable.GetIndexObject(theIndexName)

We get the name of first index using the IndexNames function of CATable. We pass it into the GetIndexObject function of CATable to get a CAIndex object that represents our index. This automation object returns information about its corresponding index. If this function fails, it returns Nothing. In that case, use ErrorCode and ErrorText functions of CAEngine to find out why.

Getting information from CATable and CAIndex

PrintResultTable also shows how to get information from CATable and CAIndex objects. This code gets the index and table elements of the Cost table:

```
numEls = theIndexObj.IndexElements
For i = 1 To numEls
    theIndexElement = theIndexObj.GetValueByNumber(i)
    theTableElement = resultTable.GetDataByElements(i)
    ...  
Next i
```

The IndexElements property of CAIndex returns the number of elements in the (first) index. The GetValueByNumber function of CAIndex gets individual index elements.

To get the individual table elements of the Cost table object, resultTable, we use the GetDataByElements function of CATable, passing in the coordinates of the element in the table.

When we retrieve an individual element of our CATable object (resultTable), we take advantage of the fact that the table is one-dimensional. Therefore, we only need to pass GetDataByElements a single number representing the position in our table. If we were dealing with two or more dimensions, however, we would need to pass GetDataByElements an array specifying the coordinates of the element of our table to retrieve. So, if we want to retrieve the element at position (4,3) of a two-dimensional table, we would write:

```
Dim W as Variant 'return element
Dim IndexPtrs(1 To 2) As Variant 'position in table
...
IndexPtrs(1) = 4
IndexPtrs(2) = 3
W = resultTable.GetDataByElements(IndexPtrs)
```

Controlling formats of atomic values

Each atomic value in a CATable can be a number, string, or one of a few other basic types (e.g., Null, Undefined, Reference, or Handle). These are returned as variants, a data structure understood by Visual Basic, specifying the type and value. The RenderingStyle property of CATable controls how the underlying Analytica value is mapped to the Visual Basic variant.

For example, it can return a numeric value as a number, or a string using the Analytica model’s number format setting. If it is formatted, an option controls whether to truncate the number of digits or to return it with full precision.

In the PrintResultTable subroutine, located in frmMain.vb, the rendering style is explicitly specified:

```
resultTable.RenderingStyle.NumberAsText = True
resultTable.RenderingStyle.FullPrecision = False
resultTable.RenderingStyle.StringQuotes = 2
```

The first line specifies that numeric values should be formatted as text according to the number format associated with the result object. For example, in the program output, we see 30.103M instead of 30102995.6639812, which would likely be displayed if we had let Visual Basic con-
catenate the numeric value to our result string. In the event that a string-valued cell occurs in the
result, it returns with explicit double quotes around the value. See “Class CARenderingStyle” on
page 70 for additional properties available through the CARenderingStyle object.

Other ways to access tables

There are several ways to access the elements of a multi-dimensional CATable. Some might be
more convenient in certain scenarios than others.

The first way is to use the GetDataByElements or GetDataByLabels methods of CATable,
shown in the code example above. In this case, you supply the coordinates of the cell whose
atomic value you wish to retrieve.

A second way is to use the Slice or Subscript methods of CATable to obtain a new CATable
object having one less dimension. By repeatedly reducing the dimensionality, you eventually
reach zero dimensions, in which case you have a single atomic value. At that point, the AtomicValue
method of CATable returns this value. The AtomicValue method is the only way to
access a scalar value (since it doesn't have a coordinate). You must use this method if you need
to generate a graph image of a slice of the full result.

A third way is to use the GetSafeArray method of CATable, to convert the multi-dimensional
array into a safe array (or into a .NET array). You can then manipulate the multi-dimensional
array directly in VB or other .NET language. Since there is no inherent ordering to Analytica
dimensions, but safe arrays and .NET arrays have an explicit ordering, you must first use the SetIndexOrder
of CATable to specify the ordering of dimensions before calling GetSafeArray. Note
that this is not necessary if you know that your array is one-dimensional.

Modifying objects

A custom application often gets input from a user or other external source to transfer into input
variables in the Analytica model. You can do this either by setting the definition of an input vari-
able, or by using a definition table.

TestTxc shows how to modify the definition of Pop_exp, which is a model input that effects the
Cost result variable. To set the definition in the example, select File > Change Population
Exposed from the main menu. A dialog appears, as shown in .

![Redefining the variable definition](image)

Enter a new definition into the field and click Ok. The main window displays the new value of
Cost. The OkButton_Click function in ChangeDef.frm is called when the Ok button is clicked
in the dialog. It modifies the definition of Pop_exp, and then calls the PrintAttributes function
that prints the result of Cost.

The function looks like this:

```vba
Private Sub OkButton_Click(ByVal eventSender As System.Object,
                           ByVal eventArgs As System.EventArgs) Handles OkButton.Click
    Dim errorText As String
```
```vba
Dim pop_exp_Object As CAObject
Dim errorCode As Short
Dim errorString As String
newDefinition = PopExposedDef.Text
pop_exp_Object = adeEngine.GetObjectByName("pop_exp")
pop_exp_Object.SetAttribute("definition", newDefinition)
errorCode = adeEngine.errorCode
If errorCode <> 0 Then
    MsgBox("This error occurred while processing your definition:
" & vbCrLf & vbCrLf & adeEngine.errorText)
    PopExposedDef.Focus()
Else
    Me.Close()
    frmMain.DefInstance.PrintAttributes("Pop_exp", "Cost")
End If
End Sub
```

This function grabs the new definition typed into the New Definition for Population Exposed field and sets it to the Pop_exp object by using the SetAttribute function of CAObject object. It then calls PrintAttributes, which evaluates the Cost object, and prints the new table.

To set a new definition for the pop_exp variable, we get the CAObject for Pop_exp, and set its definition to the definition typed in by the user. This is done with the following code:

```vba
pop_exp_Object = adeEngine.GetObjectByName("pop_exp")
pop_exp_Object.SetAttribute "definition", newDefinition
```

Whenever you call SetAttribute, you should check the ErrorCode of the CAEngine automation object (adeEngine), in case the definition is illegal.

Try entering a new definition such as Uniform(25M,35M) and click Ok. When the definition of pop_exp is changed, the result for Cost gets recomputed by ADE when ResultTable is next called for the Cost variable (when the application window is repainted).

## Graphing with ADE

Using the same graphing engine used by Analytica 4.6, you can generate a chart or graph to display an array-valued or uncertain result. In ADE 4.6, you can use the GraphToFile and GraphToStream methods of CATable. The graphs are returned in several possible image formats, such as image/png, image/bmp or image/jpeg.

The easiest way to select from the available graphing options is to open your model with Analytica. You can experiment with the settings for the various defaults or override selected variables to see how they look. When you've chosen the settings you want, save the model. ADE then uses these settings when producing result graphs for each variable.

For higher-dimensional results, some work might be necessary to select the slice of the result that will be plotted and the specific pivot (i.e., which dimensions appear on the X-axis versus in the key). The Subscript or Slice methods of CATable can be used to select the particular slice to be plotted and SetIndexOrder can be used to control the pivot. See “Class CATable” on page 63 for details. In our Tutorial.NET example, we have a one-dimensional result (Cost), and do not need to worry about slicing or pivoting.

The GraphToStream method is used to transfer the graph image directly from ADE to a user-interface method. GraphToStream is a bit more complicated to use than GraphToFile, since GraphToFile requires little more than a file name to write the image to. To use GraphToStream,
we must set up a stream in memory, allow ADE to write to that stream, and then reconstitute the image from that stream. Because .NET streams are not compatible with COM streams, you need to use the `StreamConnector` class provided with ADE. The `GraphResult_Click` routine in `frmMain` shows the use of `GraphToStream`. Select the `Graph Result` menu option from the main application window, and the results appear in a graph as shown in .

![Result graph](image)

**Conclusion**

In this tutorial, we introduced several important aspects of the Analytica Decision Engine. We saw how to create the ADE server object, open a model with ADE, get at an individual object in a model, evaluate objects, access elements in a table, and modify objects in a model. But, ADE can do a lot more!

We hope that you have learned enough about the basics so that you can now explore the more advanced features on your own. We recommend that you now read the rest of this guide to learn about what ADE can do.
Chapter 3

Using the Analytica Decision Engine Server

This chapter describes the Analytica Decision Engine server classes CAEngine, CALicense, CAObject, CATable, CAIndex, and CARenderingStyle, and the server class architecture.
Chapter 3  Using the Analytica Decision Engine Server

Server class architecture

ADE classes

ADE uses the following six classes:

- **The CAEngine class** contains methods and properties that allow you to open and close existing models, create new models, create new Analytica objects, and access Analytica objects contained in your model.
- **The CALicense class** contains methods that allow you to instantiate a CAEngine, to use a special application license code, to examine certain restrictions on your ADE license, and to access details about why a CAEngine failed to instantiate.
- **The CAObject class** contains methods and properties that allow you to set and obtain information about the Analytica objects (such as variables or modules) that you obtain from the CAEngine class.
- **The CATable class** is used to examine multi-dimensional results or to view and modify multi-dimensional definition tables (also called edit tables).
- A **CAIndex object** provides access to one dimension of a multi-dimensional CATable.
- **The CARenderingStyle class** is new in ADE 4.0, and allows you to control or alter the format in which ADE returns values.

*Note:* “CA” in these class names stands for “Class Analytica.”

The following sections describe how to access these Analytica Server objects from Visual Basic or C#.

Server class architecture

**COM, Automation, and .NET**

ADE 4.6 supports two calling conventions: COM and ActiveX Automation. COM is an early-binding convention in which the methods and data types are resolved when your application code is compiled. Automation is a late-binding convention where method calls are resolved at run time. The COM convention is somewhat more efficient, although for most applications, the difference in efficiency is far overshadowed by the time required to compute your model’s results.

In Visual Basic, the syntax for calling a method using COM or Automation is identical, and which interface is used depends on how you declare your objects. In other languages, such as C# or C++, the method of invocation can look quite different. In C# and C++, it is generally more convenient to use the COM interface. VBScript (used by the Windows Scripting Host and older versions of IIS ASP) supports only the Automation interface.

The COM interface can be used transparently from a .NET environment such as Visual Studio 2005. The .NET programming environment wraps COM objects with a .NET Interop object, which gives ADE interfaces the appearance of being .NET interfaces.

In ADE 3.1 and before, the Automation interface was the recommended convention; however, with the ADE 4.6 release, we now recommend the COM interface unless this is not an option in your programming environment (such as VBScript).

**In-process vs. out-of-process**

ADE can be launched either in-process or out-of-process. When launched in-process (ADEW), the Adew.dll library is loaded into your application’s process space. When launched out-of-process (ADE), the ADE.exe server is launched and runs in a different process. Both types of server use the same class interfaces, so the choice of which type of server to use can usually be changed by editing a single line of code, i.e., the line that instantiates the CAEngine.

In-process servers have a slight performance advantage, but come with several restrictions. First, the **apartment** threading model of ADEW must be compatible with your application’s threading model. For example, The Microsoft IIS web server (IIS 5.0 or later) does not allow you to use an apartment-threaded component under its default settings. Also, you are restricted to have only one CAEngine instance (and thus, only one model) in memory at any one time.
Out-of-process instances of ADE run in a different process, and can be configured to run on a different computer from your application. Because data must be “marshaled” across process boundaries, it is less efficient, but it is far more flexible than the in-process server. Your program can make use of multiple simultaneous instances of ADE, each with a separate model instance loaded. As such, the out-of-process server is almost always preferred for web applications because you can have one ADE instance for each session.

**Typescript**

In addition to the program interface, ADE has a fully functional command interface, known as the *typescript* language. This language is described in the [Analytica Scripting Guide](#). This language allows access to all of ADE’s functionality. The API provides a more convenient, object-oriented set of functions for communication with the engine from Visual Basic and C++ applications. A calling program can use the API functions, or it can pass typescript commands directly to the typescript interface.

**The Analytica Decision Engine architecture**

![Diagram of Analytica Decision Engine architecture]

Using ‘Command’ and ‘Send’

---

**Security permissions under IIS**

When creating a web application that uses ADE from within Microsoft’s Active Server Pages (ASP/ASPX) under Internet Information Server (IIS), you might need to configure permission settings in order to instantiate and access the ADE COM component from your program.

When creating a web application or web service, you should use the out-of-process ADE server. When your ASPX application is executed while serving a web page request, the ADE COM component is launched and accessed from a special internal Windows account name. Even though your programs can create and access ADE when run under your account, the same access might not exist for ASP or ASPX programs. To configure security permissions so that your ASPX application can use ADE, follows these steps:

1. From the Windows Control Panel, select **Administrative Tools > Component Services**.

   **Note:** If you are using ADE 32-bit on a Windows 64-bit machine, then you must instead run:

   ```
   mmc comexp.msc /32
   ```

2. In the **DCOM Config** folder, locate “Analytica Decision Engine Local Server 4.6.”

3. Select **Properties** from the right mouse menu, and select the **Security** tab.

4. Set **Launch and Activation Permissions** to **Customize**, then click **Edit**.

5. Grant local launch and local activation permissions for the account used by IIS. In IIS 5 this is usually `{computer_name}\ASPNET`. In IIS 6 & 7 this is usually `NETWORKSERVICES` or `IIS_IUSRS`. In IIS 7.5, these should be set for the Application Pool name, which is usually `"IIS AppPool\DefaultAppPool"`.

6. Save these settings. You might need to reboot of the machine to finalize these changes.

When these permissions are not properly configured, a “security exception” occurs on the line of your program that attempts to instantiate the `CAEngine`. 

---
The AdeTest program

ADE 4.6 ships with a sample program called AdeTest.exe. The executable can be found in the Examples/AdeTest/bin directory. You can use AdeTest to exercise the functionality of either the in-process (Adew.dll) or the local process (ADE.exe) versions of ADE 4.6. Using AdeTest, you can send script commands to the engine, create ADE objects, and set or call virtually any of the properties and methods of the ADE objects. If you have Visual Studio 2005 installed, you can step through the code in the Visual Studio Debugger to observe the methods being called.

AdeTest dialog

The AdeTest program dialog. The left-hand pane shows a list of ADE objects that the program is currently holding. The right side shows details of one of those objects. In the figure, there are three CAEngine instances, each with a different model open. The first CAEngine is an in-process (Adew.dll) instance, while the second two are out-of-process local servers (ADE.exe) instances. The two buttons above the left pane can be used to create additional CAEngine instances, while the Release button at the lower-right corner of the right-hand panel releases an instance. The right-hand panel shows information about the third CAEngine instance. The current values for the CAEngine properties ErrorCode, ErrorText, CurrentModule, OutputBuffer, and Photo are displayed. You can execute a typescript command by typing the command into the text box and clicking the Send button. Or you can execute any of the method of CAEngine by selecting the method in the drop-down Method box, filling in the parameters, and clicking the Execute Method button.

If you click an object in the left-hand pane, the properties for that object are displayed on the right-hand side and you can set its properties or call its methods. Thus, you can simulate a series of steps your program might execute through the graphical interface.

When a method returns an object, for example, as with CAEngine::GetObjectByName, the returned object is added to the tree on the left as a child of the object that created it. After executing a method from a class other than CAEngine, it is a good idea to glance at the corresponding CAEngine’s panel to check the ErrorCode, ErrorText, and OutputBuffer properties.

The Photo checkbox in the Analytica window is mirrored by the Photo property of the CAEngine class. By default the Photo property is False, so typescript communications between the client and ADE are not copied to the Analytica log window. Setting the Photo property to True copies all subsequent typescript communications between the client and ADE. In Visual Basic, this would be done as follows:

ADE(Photo=True)
Sample application in Excel’s Visual Basic

Another example program called excel_exam is also included in the ADE package. The program, Analytica.xls, in the excel_exam directory can be loaded into Microsoft Excel and executed as a macro. This program demonstrates the use of Visual Basic for Applications in Excel for ADE communications. This sample makes use of the local server version of ADE.

Sample ASP web application

The example in asp_exam demonstrates the use of ADE from an Active Server Pages web application. This application produces a hierarchical outline of your model structure in HTML. The readme.txt file in that directory contains instructions for configuring the web server to run the example.

When using Microsoft’s ASP, we recommend that you use the local server. By using the local server (ADE.exe), you can ensure that each web application, or even each session, uses a different version of ADE.exe. Currently, there is a limitation in ADE that prevents creation of two or more in-process server objects at the same time. Therefore, if you expect to have more than one session of ADE active at one time (as is almost always the case in web-based applications), always use the local server of ADE.

Using the ADE COM interface

From a .NET project in Visual Studio 2005

From a Visual Basic, C#, J#, ASP.NET, or C++/CLR project in Visual Studio 2005, you gain access to ADE by adding a reference to it in your project. The same technique holds with slight variations in older (pre-.NET) versions of Visual Basic and several other non-Microsoft development environments.

In Visual Studio 2005, select Add reference or References from the Project menu, and in the dialog that appears, select the COM tab (in VC++ you need to click the Add new reference button to get to the COM tab). In the list of components, locate and select one of the following:

- Analytica Decision Engine Local Server 4.6
- Analytica Decision Engine Server 4.6

For out-of-process ADE.exe servers, select the Local server. To use Adew.dll, select the (non-local) server. It is also possible to add both references into a project (the AdeTest example does this), although the need for this would be rare.

The ADE classes are exposed in the name space ADE or ADEW for the local server and in-process server, respectively. For convenience, you can add a using declaration to the top of your source files, like this:

Imports ADE ' Visual basic
using ADE;  // C#
using namespace ADE;  // C++/CLR
import ADE.*;  // J#

Of course, when using the in-process server you would type ADEW in place of ADE above. These declarations allow you to refer to CAEngine, CAObject, etc., in your code, rather than ADE.CAEngine, ADE.CAObject, etc., which makes it easy to convert from the local to the in-process ADE server should the need arise.
To begin using ADE, you need to obtain a first instantiation of CAEngine. This is done with one of the following lines:

```vbnet
dim ADE as CAEngine = new CAEngineClass ' VB
```

```c#
CAEngine ADE = new CAEngineClass(); // C#, J#
```

```csharp
CAEngine^ pAde = gcnew CAEngineClass(); // C++/CLR
```

CAEngine is the name of a particular abstract interface, while ADEW.CAEngineClass and ADE.CAEngineClass are the names of two particular object classes that implement that interface. The CAEngineClass object is the only object that you can create directly; all other ADE object instances are obtained by calling methods on existing objects.

To keep the use of the COM interface, always declare your variables with the class names CAEngine, CAObject, CATable, CAIndex, and CARenderingStyle. Avoid assigning object instances to variables declared as System.Object. This allows the compiler to perform early binding and type checking.

**Releasing objects in .NET**

In pre-.NET Visual Basic and scripting languages, the programming environment automatically ensures that COM objects are released immediately. This is not the case in VB.NET, ASP.NET, or other .NET programs. From .NET, it is important that your program explicitly releases each COM object when it is through with it. Setting a pointer to Null (or Nothing) is not sufficient, since the actual release doesn’t occur until the next garbage collection.

To release a COM object from a .NET program, you need to execute code similar to the following (C# syntax shown):

```csharp
System.Runtime.InteropServices.Marshal.ReleaseComObject(ADE);
ADE = null;
```

Releasing objects in this fashion is especially important when you are using an out-of-process COM server (e.g., ADE.CAEngine). In this case, the memory resources are predominantly consumed in the ADE process, not in your program’s process. This can cause the ADE process to run out of memory before your program’s process uses enough memory to cause an automatic garbage collection to occur. From a .NET-based web application, old ADE.exe processes linger long after a session has finished unless you explicitly release the CAEngine object.

This need to release COM objects is not unique to ADE. You must take care to release any COM object, including those provided by Microsoft, especially when those COM objects are out-of-process.

Because of this absence of deterministic destruction in .NET, it can be tedious to ensure that every COM object is released. Therefore, you might want to occasionally force an explicit garbage collection in your code, which releases all unused objects. This can be accomplished by calling:

```csharp
System.GC.Collect();
```

**From an ATL project in C++**

To use ADE 4.6 from a non-.NET C++ project, place the following two lines at the top of your source file:

```csharp
#import "ADE.exe"
using namespace ADE;
```

Or to use the in-process server, use these lines:

```csharp
#import "Adew.dll"
using namespace ADEW;
```

You need to include the ADE home directory in your include path in the project settings, or spell out the complete path in the #import declaration.

Next, obtain the first instance to an ADE engine using this code:
CoInitialize(NULL);
CAEnginePtr pAde(__uuidof(_CAEngine));
.
.
.
CoUninitialize();

`CoInitialize()` is a Windows system call that is required before the COM system can be used. If your project spans multiple code files, use this in each of your source files (or once in `stdafx.h`):

```cpp
#import "ADE.exe" no_implementation
```

And then in one file only (e.g., `stdafx.cpp`), include this line:

```cpp
#import "ADE.exe" implementation_only
```

### Using the ADE Automation interface

VBScript is an example of a scripting language, usable from Windows Scripting Host (`CScript.exe` or `WScript.exe`), pre-.NET versions of Active Server Pages, Internet Explorer, and so on. JScript is another, and many other scripting OLE-Automation compliant scripting languages are available including Perl.

These scripting languages support ActiveX Automation scripting, but not COM interfaces. Using the Automation interface, ADE can be used from these, often with no additional tools beyond a simple text editor.

For ADE releases prior to 4.6, the Automation interface was the preferred convention to use. For languages that support direct COM calls, the COM convention is now recommended in ADE 4.6. Using Automation from C++ or C# is rather tedious and not covered here.

#### From Visual Basic or VBScript

To use the Automation interface, it is not necessary to add a reference to your Visual Basic project. The syntax here is similar in other scripting languages. In Visual Basic, the code to instantiate a `CAEngine` is:

```vb
dim ADE as Object
ADE = CreateObject("ADE4.CAEngine")
```

In VBScript, and some older versions of Visual Basic, the `set` keyword is required:

```vb
dim ADE
set ADE = CreateObject("ADE4.CAEngine")
```

For the in-process server, you send the parameter `ADEW4.CAEngine` to the `CreateObject` call.

### ADE typescript: command language communication

The `Command` property and `Send` method of the `CAEngine` class allow you to use typescript commands, sent as ASCII strings to the engine, and receive the resulting output as another ASCII string. You might want to use a typescript command instead of an API method if:

- You want to perform your own parsing on ADE output (e.g., on tabular data that are output from the Analytica Decision Engine as text strings of comma-delimited text).
- No appropriate API method exists.

You perform these steps to send a typescript command to ADE:
1. Assign a text string containing the command to the Command property of your CAEngine object.

2. Use the Send method to send the command to the Engine. If the Send method returns True, then the command was processed without error by ADE.

3. Store the error code and error text (if the return code is nonzero). These two pieces of information are stored in the CAEngine properties ErrorCode and ErrorText.

4. Get the output by calling the OutputBuffer function in the CAEngine class.

Note: You can also combine the first two steps by calling CAEngine.SendCommand(cmd).

These steps are demonstrated below for various programming languages. After these simple examples, subsequent examples are given using a Visual Basic syntax, but you should have no problem extrapolating the syntax to your language of choice.

In Visual Basic

Imports ADE

Module Module1
    Sub Main()
        Dim Result, ErrT As String
        Dim ErrCode as Integer

        Dim ADE as CAEngine = New CAEngineClass
        ADE.Command = "news" 'any typescript command
        Dim SendCode as Boolean = ADE.Send
        If SendCode = False Then
            ErrCode = ADE.ErrorCode
            ErrT = ADE.ErrorText
        Else
            Result = ADE.OutputBuffer
        End If
    End Sub
End Module

In VBScript

set ADE = CreateObject("ADE4.CAEngine")
ADE.Command = "news"
If ADE.Send = False Then
    ErrCode = ADE.ErrorCode
    ErrT = ADE.ErrorText
Else
    Result = ADE.OutputBuffer
End if

In C#

using System;
using ADE;
namespace ADE_from_Csharp
{
    class Program
    {
        static void Main()
        {
            String errT, result;
            int errCode;
            CAEngine ADE = new CAEngineClass();
            ADE.Command = "news";
if (!ADE.Send()) {
    errCode = ADE.ErrorCode;
    errT = ADE.ErrorText;
} else {
    result = ADE.OutputBuffer;
}

In J#  
import ADE.*;
public class Program
{
    public static void main()
    {
        String errT, result;
        int errCode;
        ADE.CAEngine ADE = new ADE.CAEngineClass();
        ADE.set_Command("news");
        boolean sendRes = ADE.Send();
        if (!sendRes) {
            errCode = ADE.get_ErrorCode();
            errT = ADE.get_ErrorText();
        } else {
            result = ADE.get_OutputBuffer();
        }
    }
}

In C++/CLR  
using namespace System;
using namespace ADE;
void main()
{
    String ^result, ^errT;
    int errCode;
    CAEngine^ ADE = gcnew CAEngineClass();
    ADE->Command = "news";
    if (!ADE->Send()) {
        errCode = ADE->ErrorCode;
        errT = ADE->ErrorText;
    } else {
        result = ADE->OutputBuffer;
    }
}

In VC++ (without .NET)  
#import "ADE.exe"
using namespace ADE;
void main()
{
    CoInitialize(NULL);
    _bstr_t errT, result;
    int errCode;
    _CAEnginePtr pAde(__uuidof(_CAEngine));
    pAde->Command = "news";
```c
if (!pAde->Send()) {
    errT = pAde->ErrorText;
    errCode = pAde->ErrorCode;
} else {
    result = pAde->OutputBuffer;
}
CoUninitialize();
```

Errors and error handling

The CAEngine properties ErrorCode and ErrorText should be queried after any operation with ADE whenever an error is possible. Reading a value of a property from an ADE object does not change the error code. Setting the value of a property might result in an error, usually indicating an illegal value for that property. All method calls reset ErrorCode to zero if there is no error, or to a value indicating the error.

To get additional information on an error, check the OutputBuffer property of CAEngine. Any error messages that a user of Analytica would have seen appear in the output buffer.
Chapter 4

Working with Models, Modules, and Files

This section contains examples of common operations and manipulations you might perform on objects in your Analytica model.
Models and modules

Note: In VBScript, VBA, and pre-dot-NET versions of Visual Basic, the Set keyword was necessary when assigning an object to a variable. In VB.NET, the Set keyword is no longer necessary. The Set keyword is not used in the examples below.

- To create a new model:

  ```vbscript
  If ADE.CreateModel("NewModelName") Then
    'Model successfully created
  End If
  ```

  The CreateModel method only requires one parameter, a string containing a model name.

- To open an existing Analytica model:

  ```vbscript
  Dim ModName as String
  ModName = ADE.OpenModel("C:\...\Anamodel.ana")
  If ModName="" then
    'Handle Error condition here
  End if
  ```

  If a model has already been opened, that model is closed automatically before the new model is created. If the specified filename is not legal, OpenModel returns an empty string. In that case, use the ErrorCode property of CAEngine to determine the cause of the error. Be aware that an ErrorCode=2 warning is often returned even though the load is successful. For full details as to what has caused an error or warning, use the OutputBuffer property of the CAEngine. You must use the backward slash (\) for the path delimiter when using ADE. It does not support the forward slash (/).

- To add a module from a file to the currently open model:

  ```vbscript
  Dim Merge as Boolean = True
  Dim ModName as String
  ModName = ADE.AddModule("C:\...\MyLibrary.ana", Merge)
  if ModName="" Then
    'Handle error conditions here
  End if
  ```

  The FileSpec parameter should contain the path and filename of the module to be included. The Merge parameter is a Boolean variable that determines whether preexisting objects with identical names are overwritten. If Merge=True, then conflicting variables are overwritten. If Merge=False and there are conflicting variables, then the call to AddModule fails.

- To read a script file:

  ```vbscript
  If ADE.ReadScript("C:\..\MyScript.ana") Then
    'Script successfully read
  End If
  ```

  A script file can contain a list of typescript commands. Upon loading the file, the engine executes the commands contained in the file. Errors encountered while running the script file are described in the ErrorText property.

- To save a module (i.e., a subset of the current model) in a separate file:

  ```vbscript
  If ADE.SaveModuleFile("MyLibrary", "C:\...\MyLibrary.ana") Then
    'Save succeeded
  End If
  ```

  The first parameter is the module identifier, the second is the file name.

- To save the current model in a file:

  ```vbscript
  If ADE.SaveModel("C:\...\MyNewModel.ana") Then
    'Save succeeded
  End If
  ```
• To close the current model without saving:
  If ADE.CloseModel() Then "Close succeeded"

The CloseModel method takes no parameters.

ADE objects

• To create a new CAObject object:
  Dim ObjName As String = "NewVariable"
  Dim ObjClass As String = "Variable"
  Dim var As CAObject = ADE.CreateObject(ObjName, ObjClass)

The object name and the class of the object to be created are passed into the CreateObject method. Note that an identifier and not the title of the object should be used when giving the object a name. Most object-related methods use their Identifier attribute, not their Title attribute. ADE can create the following types of objects: variable, module, chance, constant, decision, index, and objective. Refer to the Analytica User Guide for more information on these object types.

• To delete an Analytica object from a model:
  Dim obj as CAObject
  If ADE.DeleteObject(obj) Then "Successful"

• To set the active module:
  ObjName = "ModuleToMakeActive"
  ObjClass = "Module"
  Var = ADE.CreateObject(ObjName, ObjClass)
  ADE.CurrentModule = Var

ADE uses a hierarchy to order objects. When an object is created, it is created inside the current module. By default, all objects are placed within the top-level module unless you set the CurrentModule property.

• To identify the current module:
  Dim module As CAObject = ADE.CurrentModule

• To obtain a CAObject object when you know the name of an Analytica variable (this is probably the most commonly used method in ADE):
  Dim Var As CAObject = ADE.GetObjectByName("IdentifierInModel")
  If Var Is Nothing Then
    'Analytica model associated with Ana
    'does not contain variable with
    'identifier "IdentifierInModel"
  End If

The method CAObject::Get is synonymous with GetObjectByName.

• You can get all Analytica object attributes using the GetAttribute method:
  UnitsOfVar = Var.GetAttribute("Units")

Use the SetAttribute method to change an attribute of an Analytica object:
  If Var.SetAttribute("definition","A/B") Then
    'Attribute Set Correctly
  Else
    'Attribute Not Set
  End If

• To access or rename the identifier of an object, use the Name property:
  Dim oldName As String = Var.Name
  Var.Name = "NewIdentifier"
For the full lists of object attributes, see Chapter 2 of *The Analytica Scripting Guide*.

## Retrieving computed results

The **CAObject** class contains three methods that cause results to be computed and returned. The **Result** method evaluates an object in your model and returns the result as a single value. This is most useful if you know that the result is a single number or single text string. The **ResultTable** method evaluates an object in your model and returns the result as a **CATable** object. Methods and properties of the **CATable** object allow you to understand what dimensions are present and to access individual elements (cells). The **Evaluate** method processes an arbitrary expression and returns the result of parsing and evaluating that expression as a multi-dimensional **CATable**.

When retrieving results, you have control over which computation mode is used to compute the result. You can compute the deterministic mid point value, or the various probabilistic views: Mean, Sample, PDF, CDF, Statistics, or Bands. Set the **ResultType** to indicate which result type you desire (default is **Mid**).

Whether you are computing a scalar or a table, your program eventually accesses individual atomic values such as numbers or text strings. You can use various **RenderingStyle** settings to control the form in which these values are returned. For example, numeric values can be returned as floating point numbers, formatted strings, or full-precision string depictions. Textual strings can be returned with or without surrounding quotes.

- To evaluate and obtain a simple result (e.g., a scalar) of an object, use the **Result** method of **CAObject**:
  ```vba
  Dim Obj As CAObject
  Dim Result
  Obj = ADE.GetObjectByName("ObjectToEvaluate")
  Result = Obj.Result
  If ADE.ErrorCode = 0 Then
    'Result was successfully retrieved
  Else
    'An error occurred
  End If
  ```
  By default, the **Result** property of **CAObject** retrieves the midpoint result of the object. It returns the result as a variant (or in .NET, as a **System.Object**). This method is convenient for retrieving the results of objects that evaluate to a scalar.

- To evaluate and obtain the result of an object as something other than the midpoint, use the **ResultType** property of **CATable** or **CAObject**:
  ```vba
  Dim Obj As CAObject = ADE.GetObjectByName("ObjectToEvaluate")
  Dim Result
  Obj = ADE.GetObjectByName("ObjectToEvaluate")
  Obj.ResultType = 1 ' get result as mean
  Result = Obj.Result
  If ADE.ErrorCode = 0 Then
    'Result was successfully retrieved as a mean
  Else
    'An error occurred
  End If
  ```
  The **ResultType** property is used to indicate the type of result that **Result** should return. Possible values are 0=Mid point, 1=Mean, 2=Probabilistic Sample, 3=PDF, 4=CDF, 5=Statistics, and 6=Probability Bands. When **ResultType**>=2, the result is always a table, even if the mid and mean are scalars. See the next section for a discussion on retrieving table results.

- To retrieve a formatted result, set properties of the object’s **RenderingStyle**:
Retrieving computed results

Chapter 4 Working with Models, Modules, and Files

Retrieving multi-dimensional results

Before describing how to obtain results from table objects (arrays with one or more dimensions), let us briefly discuss the conceptual model of a table in Analytica.

An Analytica table has the following components:

• Indexes, each of which identifies a dimension of the table
• Values in the cells of the table
• Index labels, which identify the coordinates of each cell

The number of indexes determines the dimensionality of the table. So, for example, if a table contains two indexes, then the table is two-dimensional.

The number of elements in the index determines the actual number of cells in the table. Suppose table \( T \) is composed of two indexes, \( I \) and \( J \). If \( I \) has five elements (AA, BB, CC, DD, and EE) and \( J \) has three elements (A, B, and C), then \( T \) is either a 5x3 table, or a 3x5 table, depending on your perspective.

Determining your perspective of a table is very important when working with ADE. It is up to you to tell ADE how you wish to view the table. So, for example, in the paragraph above, if you tell ADE to use index \( I \) first, followed by index \( J \), then element 2,3 would be the element described by position \( I=B, J=CC \). If, however, you tell ADE to use index \( J \) first, followed by index \( I \), then element 2,3 would be described by position \( I=C, J=BB \) (note that tables in ADE are 1-based; that is, each dimension goes from 1 to \( N \) where \( N \) is the size of the index). The method called SetIndexOrder, described below, allows you to set the order of the indexes for your table so that you can look at the table in any way you desire.

The ADE methods are very flexible in terms of how you refer to individual elements in the table. You can either refer to the individual elements by their position number or by their label names. So, for example, you can tell ADE to give you the element at position 2,1 (2 along the first index, and 1 along the second index), or you can tell ADE to give you the element described by ‘BB’, ‘A’ where ‘BB’ and ‘A’ are label names in their respective indexes. The methods most commonly used for these types of transactions (GetDataByElements and GetDataByLabels) are described below.

As discussed in the previous section, the Result and ResultType methods are used to evaluate and obtain the result of an object. For objects that evaluate to multi-dimensional results, however, it is often inconvenient to use the Result method because the output would be a long comma-delimited string in the following form:

\[
\text{Table Index1...IndexN [Value1, Value2...]}\]
Here, Index1 to IndexN are the indexes of the table, and Value1 to ValueN are the values in the table (which are filled in row by row). So, if we wanted to get at a particular element in the table after using the **Result** method, we would have to parse through the comma-delimited string returned from **Result** to get at the element of interest. Fortunately, ADE provides an ADE object of type **CATable** that provides methods to simplify the manipulation of tables.

- To evaluate and obtain the result of an object as a table use the **ResultType** method of **CAObject**:

```vba
Dim Obj As CAObject = ADE.GetObjectByName ("MultiDimObject")
Dim TableResult As CATable = Obj.ResultTable
If Not (TableResult Is Nothing) Then
    'Result table was successfully retrieved
Else
    'An error occurred
End If
```

The **ResultTable** method of **CAObject** returns an automation object of type **CATable**. **CATable** contains various methods that allow you to set, retrieve, and manipulate individual elements in the table. More than likely, the first thing that you want to do after retrieving the **CATable** object is to set the index order of the result table.

- To parse and evaluate an arbitrary expression, use the **Evaluate** method of **CAObject**.

```vba
Dim Obj As CAObject = ADE.GetObjectByName ("ContextObject")
Obj.ResultType = 2 ' Sample
Dim TableResult As CATable = Obj.Evaluate("Normal(X,Y^2) / Z")
If ADE.ErrorCode <> 0 Then
    'An error occurred
Else
    'Evaluation successful
End If
```

To use **Evaluate**, you must first obtain a **CAObject** instance. Although the expression you are evaluating might have nothing to with any specific object, the **CAObject** serves a couple of purposes. First, the **ResultType** property of the object provides a place to specify the result type that you want computed. Second, if you make use of the **NumberAsText** rendering style, the number format stored with the indicated object determines how the numbers are formatted. Often, however, the object you use is of no consequence; you can even use the top-level model object as your context object.

Comparing the previous two examples demonstrates also that there are often two ways to detect failure. The **ErrorCode** property is non-zero if an error occurred during the evaluation of a method. And for many methods, the return value is **Nothing** or **False** if it fails.

- To set the index order of a **CATable** object, use the **SetIndexOrder** method:

```vba
Dim Obj As CAObject
Dim TableResult As CATable
Dim IndexOrder (2) as String
Set Obj = ADE.GetObjectByName ("MultiDimObject")
Set TableResult = Obj.ResultTable
If Not (TableResult Is Nothing) Then
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TableResult.SetIndexOrder(IndexOrder)Then
        'Index Order set successfully
    Else
        'An error occurred in setting index order
    End If
```
The code above assumes that we are manipulating a two-dimensional table. We set the index order of this table so that Index2 is the first index, and Index1 is the second index.

In some computer languages, the first element of an array is considered position 0 (zero-based), and in other languages it is position 1 (one-based). Analytica’s Slice function, and the ADE methods are one-based. Older versions of Visual Basic are one-based, while current versions of Visual Basic and most other modern programming languages are zero-based. In the example above, the Visual Basic array was declared and used as follows:

```vbnet
Dim IndexOrder(2) As String
IndexOrder (1) = "Index2"
IndexOrder (2) = "Index1"
```

In modern Visual Basic, this declares an array that ranges from position 0 to position 2 — an array having three elements. Because the first element was not set, it contains the special value Empty. ADE can recognize whether zero-based or one-based arrays are being passed to it. So, depending on your preference, it would work equally well to use a zero-based version, for example:

```vbnet
Dim IndexOrder(1) As String
IndexOrder (0) = "Index2"
IndexOrder (1) = "Index1"
ResultTable.SetIndexOrder(IndexOrder)
```

- To retrieve an element in a table by index order, use the GetDataByElements method:

```vbnet
Dim Obj As CAObject
Dim TableResult As CATable
Dim IndexOrder (2) As String
Dim Pos (2) As Integer
Dim Element
Obj = ADE.GetObjectByName ("MultiDimObject")
TableResult = Obj.ResultTable
If Not (TableResult Is Nothing) Then
  'Result table was successfully retrieved
  IndexOrder (1) = "Index2"
  IndexOrder (2) = "Index1"
  RetValue = TableResult.SetIndexOrder (IndexOrder)
  If RetValue = True Then
    'Index Order set successfully
    Pos (1) = 2
    Pos (2) = 1
    Element = TableResult.GetDataByElements (Pos)
    If ADE.ErrorCode = 0 Then
      'element retrieved successfully
    Else
      'an error occurred
    End If
  Else
    'An error occurred in setting index order
  End If
Else
  'An error occurred
End If

Else
  'An error occurred
```
End If

This code uses `GetDataByElements` to retrieve the element at position `Index2=2, Index1=1` and stores the result to `Element`.

- To retrieve an element in a table by index labels, use the `GetDataByLabels` method:

  ```vba
  Dim Obj As CAObject
  Dim TableResult As CATable
  Dim IndexOrder (2) As String
  Dim Pos (2) As String
  Dim Element
  Obj = ADE.GetObjectByName ("MultiDimObject")
  TableResult = Obj.ResultTable
  If Not TableResult Is Nothing Then
    'Result table was successfully retrieved
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TableResult.SetIndexOrder(IndexOrder) Then
      'Index Order set successfully
      Pos (1) = "SomeLabelInIndex2"
      Pos (2) = "SomeLabelInIndex1"
      Element = TableResult.GetDataByLabels (Pos)
      If ADE.ErrorCode = 0 Then
        'element retrieved successfully
      Else
        'an error occurred
        End If
    Else
      'An error occurred in setting index order
      End If
    Else
      'An error occurred
      End If
  Else
    'An error occurred
  End If
  ``

The code above uses `GetDataByLabels` to retrieve the element at position `Index2="SomeLabelInIndex2", Index1="SomeLabelInIndex1"` and stores the result to `Element`.

- To control the format of elements obtained by `GetDataByLabels`, `GetDataByElements`, `AtomicValue`, or `GetSafeArray` methods, set `CATable`'s `RenderingStyle` properties:

  ```vba
  Dim TableResult as CATable = Obj.ResultTable
  Dim rs As CARenderingStyle = TableResult.RenderingStyle
  rs.NumberAsText = True
  rs.FullPrecision = True
  rs.UndefValue = ""
  rs.StringQuotes = 1
  Dim Element
  If TableResult.SetIndexOrder(Split("Index2;Index1",";")) Then
    Element = TableResult.GetDataByLabels( _
               Split("SomeLabel1,SomeLabel2","",""))
    If ADE.ErrorCode=0 Then
      ' Element retrieved successfully
    End If
  End If
  ```
• To retrieve the whole table into a Visual Basic or .NET array in one call, use the
GetSafeArray method:

```vbnet
Dim Obj As CAObject
Dim TableResult As CATable
Dim IndexOrder (2) As String
Dim Pos (2) As Integer
Dim TheWholeTable
Obj = ADE.GetObjectByName("MultiDimObject")
TableResult = Obj.ResultTable
If Not (TableResult Is Nothing) Then
    'Result table was successfully retrieved
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TableResult.SetIndexOrder(IndexOrder) Then
        'Index Order set successfully
        TheWholeTable = TableResult.GetSafeArray
        If ADE.ErrorCode = 0 Then
            'table retrieved successfully
        Else
            'an error occurred
        End If
    Else
        'An error occurred in setting index order
    End If
Else
    'An error occurred
End If
```

The code above uses GetSafeArray to store the entire table in TheWholeTable. The elements of each dimension associated with the table returned from GetSafeArray are indexed 1 to N, where N is the length of the dimension. The lower bound of the safe array can be changed to zero using this code prior to calling GetSafeArray:

```vbnet
TableResult.RenderingStyle.SafeArrayLowerBound = 0
```

The syntax for reading a multi-dimensional result in a .NET array in C# is worth mentioning:

```csharp
Array theWholeTable = (Array) tableResult.GetSafeArray();
```

• To determine the number of dimensions of the table, use the NumDims property:

```vbnet
NumDimensions = ADE.Get("MultiDimObject").ResultTable.NumDims
```

• To get the index names associated with the table, use the IndexNames method:

```vbnet
Dim CurIndexName As String
Dim Obj As CAObject = ADE.GetObjectByName("MultiDimObject")
Dim TableResult As CATable = Obj.ResultTable
Dim NumDimensions As integer = TableResult.NumDims
Dim I as Integer
For I = 1 To NumDimensions
    CurIndexName = TableResult.IndexNames(I)
    MsgBox "Current index is " & CurIndexName
Next I
```

The IndexNames method returns the index names of the table in the order specified to SetIndexOrder. If SetIndexOrder has not been set for the CATable, then the default order of the indexes is returned.

• To associate CAIndex objects with your table, use the GetIndexObject method of CATable:
Dim Obj As CAObject = ADE.GetObjectByName("MultiDimObject")
Dim Res As CATable = Obj.ResultTable
Dim NumDimensions As Integer = Res.NumDims
Dim CurIndexName As String = Res.IndexNames(NumDimensions)
Dim IndexObj As CAIndex = Res.GetIndexObject(CurIndexName)

The example above retrieved the last CAIndex object, with respect to the index order, from the table. The CAIndex object provides properties and methods that allow you to obtain information about the respective index.

- To get the number of elements in the index, use the IndexElements property:

  Dim Obj As CAObject = ADE.GetObjectByName("MultiDimObject")
  Dim Res As CATable = Obj.ResultTable
  Dim NumDimensions As Integer = Res.NumDims
  Dim CurIndexName As String = Res.IndexNames(NumDimensions)
  Dim IndexObj As CAIndex = Res.GetIndexObject(CurIndexName)
  Dim NumElsInIndex As Integer = IndexObj.IndexElements

- To get an index label at the specified position in the index, use the GetValueByNumber method:

  Dim I As Integer
  Dim Obj As CAObject = ADE.GetObjectByName("MultiDimObject")
  Dim Res As CATable = Obj.ResultTable
  Dim NumDimensions As Integer = Res.NumDims
  Dim CurIndexName As String = Res.IndexNames(NumDimensions)
  Dim IndexObj As CAIndex = Res.GetIndexObject(CurIndexName)
  Dim Str As String = "The elements in the index are: " & vbCrLf
  For I = 1 To IndexObj.IndexElements
    Str = Str & IndexObj.GetValueByNumber(I) & " \\
  Next I
  MsgBox Str

- To get at the position of an index label in an index, use the GetNumberByValue method:

  Dim Obj As CAObject = ADE.GetObjectByName("MultiDimObject")
  Dim Res As CATable = Obj.ResultTable
  Dim IndexName As String = Res.IndexNames(Res.NumDims)
  Dim IndexObj As CAIndex = Res.GetIndexObject(IndexName)
  Dim IndexPosition As Integer
  IndexPosition = IndexObj.GetNumberByValue("SomeIndexLabel")
  If ADE.ErrorCode = 0 Then
    ' the index position was successfully retrieved
  Else
    ' an error occurred
  End If

- To obtain the scalar value in a zero-dimensional array:

  Dim Res As CATable = ADE.Get("SomeObject").ResultTable
  Dim x As Object
  If Res.NumDims = 0 Then
    x = Res.AtomicValue
  Else
    ' handle the array case.
  End If

Sometimes, it is not possible to know in advance whether the evaluation of an object returns
Retrieving computed results

Chapter 4 Working with Models, Modules, and Files

A multi-dimensional result or a scalar. In this case, use **ResultTable**. If the result happens to be a scalar, **NumDims** returns zero. In this case, the so-called “array” isn’t an array at all, but rather contains a single atomic value. It is also possible to end up with a zero-dimensional array after calling the **CATable::Slice** or **CATable::Subscript** methods. To obtain the atomic value, use the **CATable::AtomicValue** method.

- To reduce dimensionality in **Slice** and **Subscript** operations:

  ```vbnet
  Dim PandL As CATable = ADE.Get("P_n_L_Statement").ResultTable
  Dim CatIndex As CAIndex = PandL.GetIndexObject("Categories")
  Dim Expenses As CATable = PandL.Subscript(CatIndex, "Expenses")
  Dim Year As CAIndex = Expenses.GetIndexObject("Year")
  Dim InitialExpense
  InitialExpense = Expenses.Slice(Year, 1).AtomicValue
  ```

  The **Slice** and **Subscript** methods of **CATable** return a new **CATable** object with the number of dimensions reduced by one. These methods are similar to the Slice and Subscript functions built into Analytica. Slice returns the Nth slice (by position) along a given dimension. **Subscript** returns the slice corresponding to a specified index value.

Creating tables and setting values in tables

We can apply the same methods described above to definition tables to retrieve values from result tables. A **definition table**, as the name suggests, is when the definition of an object is a **Table** function (also known as an **edit table** in Analytica).

The value of an Analytica variable (accessed via **ResultTable**) can be an array — not because it was defined by a definition table, but simply because it is defined as an expression or function that returns an array value.

When using an edit table, you need to pay careful attention to whether you are passing general expressions into each table cell, or just literal strings. The **RenderingStyle:GeneralExpression** property determines how string values that you send to the table are interpreted. By default, **GeneralExpression=true**, which means that if you set a cell value to the string "Revenue", this is an actual expression consisting of one variable identifier, and not a literal string. If you are populating a definition table with literal constants (as you might an input table to your model), you should either use **RenderingStyle:GeneralExpressions=false**, or remember to prepend and append quotation marks on all literal string values.

An object defined as a definition table does not necessarily produce the same table when **ResultTable** is called. After all, the definition table can be defined to be an array of identifiers. When **ResultTable** is called, each identifier’s result is evaluated, and a new table is produced (which would be different than the definition table). If identifiers evaluate to arrays, the result table might have more dimensions than the definition table.

- To get the definition table of an object as a **CATable**, use the **DefTable** method of **CAObject**:

  ```vbnet
  Dim Obj As CAObject
  Dim TableDef As CATable
  Obj = ADE.GetObjectByName("MultiDimObject")
  TableDef = Obj.DefTable
  If Not TableDef Is Nothing Then
    'Definition table was successfully retrieved
  Else
    'An error occurred, or definition is not a table
  End If
  ```

  After the definition table is retrieved, we can use all the same methods described in the section above (**GetDataByElements**, **GetDataByLabels**, **SetIndexOrder**, etc.) to retrieve elements in the table and to obtain information about the indexes in the table. We can also
use the same method that we used above in determining whether the result of the object was multi-dimensional or scalar to determine whether the definition of the object is a table or scalar:

```vba
Dim Obj As Object
Dim TableDefinition As Object
Dim ScalarDefinition

Obj = ADE.GetObjectByName ("SomeObject")
TableDefinition = Obj.DefTable
If TableDefinition Is Nothing Then
    ScalarDefinition = Obj.GetAttribute ("definition")
    If ADE.ErrorCode = 0 Then
        'you have a scalar definition
    Else
        'an error occurred
    End If
Else
    'you have a table definition
End If
```

- To set an element in a table by index order, use the `SetDataByElements` method of `CATable`:

```vba
Dim Obj As CAObject
Dim TableDef As CATable
Dim IndexOrder (2) As String
Dim Pos (2) As Integer
Dim Element

Obj = ADE.GetObjectByName ("MultiDimObject")
TableDef = Obj.DefTable
If Not TableDef Is Nothing Then
    'Definition table was successfully retrieved
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TableDef.SetIndexOrder (IndexOrder) Then
        'Index Order set successfully
        Pos (1) = 2
        Pos (2) = 1
        Element = "'ABC'" ' Notice the extra quotes
        If TableDef.SetDataByElements(Element,Pos) Then
            'element successfully set
            If TableDef.Update Then
                'model successfully updated
            Else
                'error updating def in model
            End If
        Else
            'an error occurred
        End If
    Else
        'An error occurred in setting index order
    End If
Else
```

42 Analytica® Decision Engine User Guide
This code uses `SetDataByElements` to set the element at position `Index2=2, Index1=1` to `Element`. Note the use of the quotes around `ABC`. Here, since `ABC` is single quoted, we are putting the string “ABC” in the table. If we instead set `Element` to “ABC”, then the expression `ABC` would be placed in the table. In the latter case, `ABC` would likely be a variable. If an identifier, `ABC`, did not exist in the model, then an error would have occurred while trying to set the element in the latter case. The code then used `Update` to update the model with the new definition. It is important to note that the model containing the object is not updated until `Update` is called. Therefore, if `Update` is not called, and the result of a node that depends on this object is later calculated, the old definition of this object is still used. The other important thing to note is that `Update` functions very differently for result tables than for definition tables. For result tables, `Update` retrieves the result from the specified object again. Therefore, it overwrites any changes that were made to the object using `SetDataByElements` and `SetDataByLabels`.

To set an element in a table by index labels, use the `SetDataByLabels` method of `CATable`:

```vba
Dim Obj As CAObject
Dim TabDef As CATable
Dim IndexOrder (2) as String
Dim Pos (2) as String
Dim Element

Obj = ADE.GetObjectByName("MultiDimObject")
TabDef = Obj.DefTable
If Not TabDef Is Nothing Then
    'Definition table was successfully retrieved
    TabDef.RenderingStyle.GeneralExpression = False
    IndexOrder (1) = "Index2"
    IndexOrder (2) = "Index1"
    If TabDef.SetIndexOrder(IndexOrder) Then
        'Index Order set successfully
        Pos (1) = "SomeLabelInIndex2"
        Pos (2) = "SomeLabelInIndex1"
        Element = "ABC"
        If TabDef.SetDataByLabels(Element,Pos) Then
            'element set successfully
            If TabDef.Update Then
                'model successfully updated
            Else
                'an error occurred
            End If
        Else
            'an error occurred
        End If
    Else
        'An error occurred in setting index order
    End If
Else
    'An error occurred, or definition is scalar
End If
```

The code above uses `SetDataByLabels` to set the element at position `Index2="SomeLabelInIndex2", Index1="SomeLabelInIndex1"` to `Element`. In this example, the `RenderingStyle.GeneralExpression` property was set to `False`. This
Adjusting how values are returned

Analytica models can contain several different data types for values in attributes or in the cells of a table or index. Data types include floating point numbers, textual strings, the special values Undefined and Null, references, and handles to other objects. When these data types are...
Chapter 4 Working with Models, Modules, and Files

Adjusting how values are returned

returned and ultimately mapped to data types in the programming language you are using, you might want or need to alter how the values are returned. You can do so using RenderingStyle.

The CAObject, CATable, and CAIndex objects all contain a property called RenderingStyle, which returns a CARenderingStyle object. Properties of the rendering style can be changed to alter how values are returned. You can also control whether safe arrays returned by Analytica are 1-based or 0-based. These settings impact CAObject::GetAttribute and CAObject::Result; they also impact CATable::GetDataByElements, CATable::GetDataByLabels, CATable::AtomicValue, CATable::GetSafeArray, and CAIndex::GetValueByNumber.

When transferring values to cells in a DefTable, you can also control whether the cells are populated by literal strings and values, or by general expressions. This is controlled by the GeneralExpression property of CARenderingStyle.

The DefaultRenderingStyle and DefaultDefTableRenderingStyle properties of CAEngine can be set once just after the CAEngine has been instantiated to set the rendering style globally. For example, if you always use zero-based arrays, this can be specified once.

- Retrieving numeric values as numbers:
  ```vba
  obj.RenderingStyle.NumberAsText = False
  Dim x As Double = obj.Result
  ```
  Numeric values are returned as numbers by default, so unless NumberAsText is set to True at some point, there is no need to specify this explicitly.

- Retrieving numeric values as formatted strings:
  ```vba
  Dim TableResult As CATable = Obj.Evaluate("1 / 3 * 10 ^ 6")
  TableResult.RenderingStyle.NumberAsText = True
  TableResult.RenderingStyle.FullPrecision = False
  Dim s As String = TableResult.AtomicValue
  ```
  The number format associated with Obj is used to format the numeric value. A suffix style with four digits returns “333.3K” for this example.

- Retrieving numeric values as strings with no loss of precision:
  ```vba
  Dim TableResult As CATable = Obj.Evaluate("1 / 3 * 10 ^ 6")
  TableResult.RenderingStyle.NumberAsText = True
  TableResult.RenderingStyle.FullPrecision = True
  Dim s As String = TableResult.AtomicValue
  ```
  Analytica continues to use the number format associated with Obj, but the significant digits is increased to avoid any loss in precision. So, suffix, exponential, fixed point, and percent formats are not truncated. If a date, integer, or Boolean format is used, some truncation might still occur. In the example, the return value would be 333.333333333333.

- Retrieving string results without quotation marks:
  ```vba
  tab.RenderingStyle.StringQuotes = 0
  ```

- Retrieving string results with explicit quotation marks:
  ```vba
  tab.RenderingStyle.StringQuotes = 1 ' for single quotes
  tab.RenderingStyle.StringQuotes = 2 ' for double quotes
  ```

- Using a custom value for Undefined:
  ```vba
  ADE.DefaultRenderingStyle.UndefValue = ""
  ```
  By default, the special value Undefined is returned as a the special Windows variant type Empty. There are some scripting languages that cannot deal with the Empty data type, so if you encounter this problem, you might want to change this value.

- Setting the cells of a definition table to string values:
  ```vba
  defTab.RenderingStyle.GeneralExpression = False
  defTab.SetDataByElements("A & B",inds)
  ```
  In this example, the indicated table cell is set to the string value "A & B". When this table is evaluated, this cell’s result is a string containing the five characters "A & B".
• Setting the cells of a definition table to expressions:
  
  ```plaintext
  defTab.RenderingStyle.GeneralExpression = True
  defTab.SetDataByElements("A & B",inds)
  ```
  
  Here the cell is set to the expression "A & B". When this table is evaluated, the variable named A and the variable B is evaluated, and their results are coerced to strings and concatenated by the & operator.

  You can set table cells to literal strings with `GeneralExpression=True`, but you must embed explicit quotation marks in the expression. For example:

  ```plaintext
  defTab.RenderingStyle.GeneralExpression = True
  defTab.SetDataByElements("'A & B'",inds)
  ```

  GeneralExpression=True by default.

### Terminating an in-progress computation

Methods such as `CAObject.ResultTable`, `CAObject.Result`, or `CAObject.Evaluate` can initiate lengthy evaluations that could tie up your application. Some models can take many minutes, or even several hours, to compute the result. Normally, your call to `ResultTable` does not return until the result is fully computed.

You might want to provide your end user with the capability to abort the current computation, such as when a "break" key or button is pressed. Alternatively, you might want to terminate the current computation if your application is suddenly being terminated while a lengthy computation is still processing, so that ADE also terminates.

To implement the ability to abort a computation, you need to have some form of multi-threading in your application. The thread that calls ADE is occupied waiting for ADE to return, so some other thread in your application must detect the request to terminate the computation. When this request is detected, the second thread communicates this request to ADE through a global system event object. You must obtain the information required to locate this global event object from ADE before you have started the length computation. Each `CAEngine` instance has its own event object with a unique global name, but the same event object applies to the same `CAEngine` instance for the entire lifetime of the `CAEngine` instance.

To obtain the event object (using Windows Platform SDK calls):

```plaintext
Dim abortEventName As String
Dim abortHandle as Handle ' This needs to be global
ade.SendCommand("GetProcessEventInfo('Abort Event Object')")
abortEventName = ade.OutputBuffer
abortHandle = OpenEvent(EVENT_MODIFY_STATE, FALSE, abortEventName )
...
' Launch the computation
tab = obj.ResultTable
```

In a separate thread that detects a request to terminate the computation, the following code sends that request to ADE (using Windows Platform SDK calls):

```plaintext
SetEvent(abortHandle)
```

Note that `OpenEvent` and `SetEvent` are Windows Platform SDK calls, not part of ADE. Also notice that the `abortHandle` variable must be a global that is accessible from both threads. However, the second thread does not require access to the ADE objects themselves. Alternatively, the `abortEventName` can be shared and the second thread can call `OpenEvent`.

When the event has been flagged, ADE backs out of the current computation and returns from the current method. A small delay might be experienced while ADE backs out of the current computation. When it has returned, the `CAEngine.ErrorCode` is set to 78 ("Computation aborted"). Your application might continue using the same ADE instance as it would have prior to the call that was aborted.
Instantiating CAEngine using CALicense

To start using ADE, the first thing you need to do is instantiate a CAEngine object. You have the option of instantiating your CAEngine object directly, or you can instantiate a CALicense object first and use it to instantiate your CAEngine object. When you’ve successfully obtained a CAEngine object, it doesn’t matter which of these two methods you used to get it. The difference is that if you use a CALicense object to instantiate your CAEngine, more information about why it failed is available. In particular, if the failure is due to a license code problem, your application has an opportunity to handle the error gracefully.

If you are creating an ADE-based application that are to be redistributed to many end users, who would otherwise not have an ADE license, you need to make arrangements with Lumina to license ADE for distribution with your application. This form of licensing requires your application to provide a special type of license code to ADE, called an application license code, since your end users usually do not have a license code of ADE on their computer. Note that a license to redistribute ADE in this fashion is not included as part of the standard ADE license agreement, and additional license fees apply. To use an application license code, you must use a CALicense to instantiate your CAEngine, since your application uses the CALicense object to supply the license code to Analytica.

The steps for instantiating a CAEngine using a CALicense are as follows, e.g.:

- **In VB**
  ```vbnet
  Imports ADE
  ...
  Dim license As CALicense = New CALicense
  Dim ade As CAEngine = license.NewCAEngine
  If (ade Is Nothing) Then
    ' substitute error handling routine here
    ReportError(license.ErrorText)
  End If
  ```

- **In C#**
  ```csharp
  Using ADE;
  ...
  CALicense license = new CALicense();
  CAEngine ade = license.NewCAEngine();
  if (ade == null) {
    ReportError(license.ErrorText);
  }
  ```

If you have an application license code, insert a call to SetApplicationLicenseCode:

- **SetApplicationLicenseCode**
  ```csharp
  license = new CALicense
  license.SetApplicationLicenseCode("1234-5678-ABCD-EFGH-IJKL")
  ade = license.NewCAEngine
  ```

Using the Analytica Graphing Engine

When you have a CATable result with at least one dimension, you can obtain a graph of the result as an image. One use of this is to embed graphs as JPEG images in a web page that uses ADE on the back end.

Obtaining the graph of a result requires the following steps:

1. Select the appropriate graph settings, such as chart type, axis range settings, colors, fonts, and so on. The easiest way is to open the model in Analytica Enterprise, and select the settings you want for each variable using the Graph Setup dialog.

The graph template you create using the Graph Setup dialog is stored in the GraphSetup...
attribute of the object. You can copy the **GraphSetup** attribute from an existing variable if you need to change the style template.

2. From ADE, obtain a **CATable** with the result to be graphed.

3. Set the **GraphWidth** and **GraphHeight** properties of the **CATable** object to indicate the desired size of the graph in pixels.

4. If your result has more than two dimensions, use one of the following options:
   
a. call **Slice** or **Subscript** to reduce the dimensionality to the desired dimensionality for the plot (usually one dimension if there is no key or two dimensions if there is a key).
   - If you have more than one dimension, call **SetIndexOrder** to select the desired pivot for the graph.
   
   or

   b. set **GraphWithStoredPivot** to **true**. Use this option to produce the same slice and pivot as seen when viewed in desktop Analytica.

3. If you are sending the graph to an output stream, obtain a Windows **IStream** interface to the stream. If you have a .NET Stream (**System/io/Stream**), you need to use a wrapper class (see below).

4. Call either the **GraphToStream** or **GraphToFile** methods of **CATable**, depending on where you want the graph written to. The graph can be created in different MIME types (e.g., **image/JPEG**).

If you are able to view the result graph in Analytica with no slicers, then steps 4 and 5 are unnecessary.

- Writing a result graph to a file:
  ```vba
  Dim res As CATable = obj.ResultTable
  res.GraphWidth = 640
  res.GraphHeight = 400
  If res.GraphToFile("C:\Temp\Result.JPG","image/JPEG") Then
    ' success
  End If
  ```

- Dynamically generating a result graph from an ASP.NET web page:
  ```vbc
  <% Response.ContentType = "image/JPEG"
  Dim varName As String = Request.QueryString("var")
  Dim ADE As CAEngine = Session("ADE") ' assume existing session
  Dim res As CATable = ADE.Get(varName).ResultTable
  res.GraphWidth = 640
  res.GraphHeight = 400
  Dim stream As StreamConnector = New StreamConnector( Response.OutputStream)
  If res.GraphToStream( stream, "image/JPEG") Then
    ' success
  End If
  %>
  ```

In this example code, **Response**, **Request**, and **Session** are Active Server Page objects. The HTTP in the client browser would contain a tag like this:

```html
<img src="http://www.acme.com/Myapp/graph.aspx?var=Profit">
```

When Microsoft introduced .NET, they did not make the base **Stream** class interface in .NET compatible with the **IStream** interface in Windows. Because of this, it is necessary to create a stream wrapper that implements the **IStream** interface around the .NET **Stream** before passing it to **GraphToStream**. This wrapper, class **StreamConnector**, is included in the example AdeTest. To use the example above, add the file **StreamConnector.vb** to your project.
This chapter lists the properties and methods for the six ADE server classes CAEngine, CALicense, CAObject, CATable, CAIndex, and CARenderingStyle.
ADE server classes

The five ADE server classes are CAEngine, CAObject, CATable, CAIndex, and CARenderingStyle. They are listed below in that order, with a complete description of the properties and methods of each class.

Class CAEngine

Properties

Command

Description Sets a typescript language command for execution by the ADE Automation Server. The Send method causes Command to be sent to ADE for execution. For the list of typescript commands, see the Analytica Scripting Guide.

Data type string

Access read/write

Usage ADE.Command = "value obj1"

CurrentModule

Description The currently open module.

Data type CAObject

Access read/write

Usage Dim Obj As Object
Set Obj = ADE.CurrentModule

Remarks Newly created objects are placed into CurrentModule; so, you should set CurrentModule before creating any new objects. Setting CurrentModule = Nothing means that no module is open, so all new objects are created in the top-level Module or Model of the currently opened model.

API errors 44 – "Module could not be set"

DefaultDefTableRenderingStyle

Description The default rendering style controlling how definition table values are transferred to and from ADE. All definition tables returned from CAObject::DefTable inherit these settings when they are first created.

Data type CAREnderingStyle

Access read/write

Usage ADE.DefaultDefTableRenderingStyle.GeneralExpression = false

DefaultRenderingStyle

Description The default rendering style controlling how result values are returned from ADE. All CAObject instances inherit this rendering style when they are created.

Data type CAREnderingStyle

Access read/write

Usage ADE.DefaultRenderingStyle.StringQuotes = 2
ErrorCode
Description  Returns the error code generated by the last communication with the Analytica Decision Engine Server. The property **ErrorCode** should be checked after setting and retrieving critical **CAEngine** properties and calling **CAEngine** methods. An **ErrorCode** of zero indicates the last action was successful.

Data type  integer
Access  read
Usage  Dim x As Integer
       x = ADE.ErrorCode

ErrorText
Description  Short text explanation of error from **ErrorCode**.

Data type  string
Usage  Dim x As String
       x = ADE.ErrorText
Access  read

Flags
Description  A bit field of flags that controls certain behaviors of the ADE engine. Currently there is only one bit in use.  

- 1 = Allow hiding and unhiding of definitions (off by default)

When this bit is off, an error results if your code, or the model (e.g., a button) attempts to change a **Att__cloakDefn** attribute, which controls whether definitions are hidden or unhidden. Keeping this off ensures that an application using a model doesn’t gain access to a definition that a model builder hid from Analytica Enterprise.

Data type  unsigned long
Usage  In VB, the bit-OR operator is OR:
       ADE.Flags = ADE.Flags OR 1

In C#, the bit-OR operator is |:
       ADE.Flags = ADE.Flags | 1
Access  read/write

Log
Description  A record of all commands sent to the ADE typescript and the results received from those commands, when the **Photo** property is true.

Data type  string
Usage  Dim x As String
       x = ADE.Log
Access  read

OutputBuffer
Description  A text string buffer that contains the result of the last typescript (i.e., using the **Command** property and **Send** method) interaction with the ADE.

Data type  string
Usage  Dim x As String
       x = ADE.OutputBuffer
Chapter 5: ADE Server Class Reference

Class CAEngine

Access read

Photo

Description When Photo is True, ADE records all typescript commands and results into the Log property.

Data type boolean

Access read/write

Usage ADE.Photo = True

Remarks Setting Photo property to True slows down computation speed of the engine.

Methods

AddModule(fileName, merge)

Description Adds a module from file fileName into the CurrentModule. The merge parameter currently has no effect and should be set to True.

Parameters fileName – string
merge – Boolean

Return value ModuleName – string

Usage ModName = ADE.AddModule("C:\MYMOD\MYMOD.ANA", True)

API errors 39 – “Module could not be found”

CloseModel

Description Closes the model.

Usage ADE.CloseModel

CreateObject(objName, objClass)

Description Creates a new Analytica object with identifier objName and class objClass in the CurrentModule and returns it as a CAObject.

Parameters objName – string
objClass – string

Return value CAObject

Usage Dim obj As CAObject
Set obj = ADE.CreateObject("NewVar","Chance")

Remarks objClass can be one of the following values: Decision, Variable, Chance, Constant, Index, Module, Objective, Determ, Alias, or Formnode.

API errors 40 – “Object could not be created”
41 – “Invalid name for object”
42 – “Object name already in use”
48 – “Invalid object class”

CreateModel(modelName)

Description Creates a new Analytica model with identifier modelName.

Parameters modelName – string

Return value Boolean (success or failure)

Usage boolval = ADE.CreateModel("MyNewModel")

API errors 45 – “Model could not be created”
DeleteObject(obj)

Description Deletes CAObject obj from the current model.

Parameters obj – CAObject

Usage Dim Obj As CAObject
Set Obj = ADE.GetObjectByName("ObjToDelete")
ADE.DeleteObject (Obj)

API errors 41 – "Invalid object"

GetObjectByName(objName)

Description Returns an object of type CAObject for an existing Analytica object with identifier objName.

Parameters objName – string

Return value CAObject

Usage Dim Obj As CAObject
Set Obj = ADE.GetObjectByName("MyObject")
Set Obj = ADE.Get("MyObject") 'alternate equiv. form

API errors 41 – "Invalid name for object"

MonitorProcess(pid)

Description Sets up a monitor thread inside ADE to detect the termination of the process with the indicated process id, and to terminate the ADE process if the indicated pid terminates first.

Parameters pid – An integer process id, which must be on the same machine as the ADE process.

ADE.MonitorProcess( pid )

Remarks It is useful to call this immediately after obtaining a CAEngine object, so that if you stop your program prematurely while debugging, or your own code crashes without releasing the CAEngine object, the ADE process will terminate along with your program.

Requires release 4.2.3 or later.

API errors 85 – MonitorProcess(pid) could not open the indicated process.
See also ADE.OutputBuffer for additional elaboration for why it failed.

OpenModel

Description Reads a model from a disk file and opens it as the current model.

Parameters FileSpec – string (the filename containing the model)

Return value ModelName – string (actual model name)

Usage modName = ADE.OpenModel("C:\TMP\MYMODEL.ANA")

Remarks Failure should be detected by checking whether the return value is "", not by checking for a zero ErrorCode. It is possible that some errors or warnings might occur during loading, and is thus reflected in the ErrorCode, ErrorText, and OutputBuffer properties, even though the load was successful.

API errors 2 – Warning (but load was successfully completed)
3 – Lexical error (load was only partially successful)
4 – Statement error (load was only partially successful)
39 – "Model could not be found"
ReadScript(filePath)

Description  Reads an Analytica script file and executes it.
Parameters  filePath – string
Usage  ADE.ReadScript("C:\TMP\SCRIPT.MOD")
API errors  39 – “Script file could not be found”

ResetError

Description  Resets the error code, error text string associated with the error code, and the output buffer to default values. This function is normally used internally, but could be useful in other circumstances as well.
Usage  ADE.ResetError

SaveModel(filePath)

Description  Saves the model to file filePath.
Parameters  filePath – string
Usage  ADE.SaveModel("C:\TMP\CHANGES.ANA")
API errors  46 – “Model could not be saved”  
49 – “There is no model to save”

SaveModuleFile(modName, filePath)

Description  Saves module with identifier modName into file filePath.
Parameters  modName – string
filePath – string
Return value  Boolean (success or failure)
Usage  b = ADE.SaveModuleFile("Function_lib", "C:\TEMP\NEWMOD.ANA")
API errors  41 – “Invalid name for object”  
46 – “Module could not be saved”

Send

Description  Sends the string contained in the Command property as a command to be executed by ADE. See the Analytica Scripting Guide for details of commands and syntax.
Return value  Boolean (success or failure)
API errors  1 – “Unimplemented” 
2 – “Warning” 
3 – “Lexical error”  
4 – “Statement error”  
5 – “Expression error”  
6 – “Execution error” 
7 – “System error” 
8 – “Fatal error” 
9 – “Undefined variable error” 
10 – “Aborted”

SendCommand(command)

Description  Sends the string command property as a typescript command to be executed by ADE. See the Analytica Scripting Guide for details of commands and syntax.  
SendCommand is a single method that is faster way to execute a typescript command than using the Send method. Using Send requires these two statements to execute a command.
ade.Command = "profile Val"
b = ade.Send()

This can be done with a single SendCommand statement.

b = ade.SendCommand("profile Val")

## Return value
Boolean (success or failure)

## API errors
1 – "Unimplemented"
2 – "Warning"
3 – "Lexical error"
4 – "Statement error"
5 – "Expression error"
6 – "Execution error"
7 – "System error"
8 – "Fatal error"
9 – "Undefined variable error"
10 – "Aborted"

---

### Class CALicense

A CALicense object can be obtained directly, for example:

```javascript
license = new CALicense;
```

Or:

```javascript
license = CreateObject("CALicense")
```

The CALicense provides a method for instantiating a CAEngine, and provides details about why such an instantiation failed, which would otherwise not be available if you instantiate the CAEngine directly. It also provides some information about limitations in your license to use ADE.

A CALicense instance can be obtained even if your ADE license code is invalid, expired, etc. This makes it possible for your application to say "failed because ....".

#### Properties

##### AvailableLicenseInstances

**Description** Number of additional ADE instances that can still be instantiated using the current license, beyond those that are already running.

**Data type** integer

**Access** read

**Usage** nAvail = license.AvailableLicenseInstances

**Remarks** Your license to use ADE might or might not limit the number of instances of ADE that can be simultaneously active on the same computer. For licenses that do impose a limit, this property shows how many additional ADE instances (equivalent to the number of CAEngine instances) can be created on this computer within the limit imposed by the license.

##### CanUseOptimizer

**Description** Indicates whether your ADE license allows your models to make use of the Optimizer. If you don’t have this ability, then models that use LpDefine, QpDefine or NlpDefine functions cannot perform those optimizations within ADE. This flag makes it possible to detect that limitation before actually starting your application.

**Data type** boolean

**Access** read
Usage if (license.CanUseOptimizer){ ... }

**errorCode**

**Description** Status code (reason for failure) from the previous method call. In particular, after calling the `CALicense.NewCAEngine` method, this provides information about the cause of the failure.

Descriptive text for any error code can be obtained using the `errorCode` property. Some codes that could be encountered include:

- 71 – “The maximum number of CAEngine instances allowed are already in use”
- 72 – “Invalid license code”
- 73 – “Stale license code”
- 74 – “Expired license code”
- 75 – “No ADE license code is present”
- 76 – “Not an application license code” (from `SetApplicationLicenseCode` method)

**Data type** integer

**Access** read

**Usage** `errCode = license.ErrorCode`

**errText**

**Description** Status text describing the reason for a failure in the previous method call. In particular, after calling the `CALicense.NewCAEngine` method, this provides information about the cause of the failure.

**Data type** string

**Access** read

**Usage** `errDescription = license.ErrorText`

**maxLicenseInstances**

**Description** Total number of ADE instances allowed on current license, including any currently running.

**Data type** integer

**Access** read

**Usage** `nAvail = license.MaxLicenseInstances`

**Remarks** Your license to use ADE might or might not limit the number of instances of ADE that can be simultaneously active on the same computer. For licenses that do impose a limit, this property provides access to what that number is (which will be greater than 0). If you have no limit, this is zero.

**RlmHostId**

**Description** The Reprise License Manager host id (used for license activation and validation) for the computer running the ADE process.

**Data type** string

**Access** read

**Usage** `hostId = License.RlmHostId`

**Remarks** Requires build 4.2.3 or later.

**RlmPath**

**Description** The path used by the Reprise License Manager when searching for a valid license.
**Chapter 5  ADE Server Class Reference**

**SetApplicationLicenseCode**

| Description | Specifies an ADE license code that is to be used for the instantiation of a **CAEngine** when **CALicense.CAEngine** is called. When this is used, a valid ADE license code does not need to be stored in the system registry, and ADE runs according to the licensed features of the specified license code, which might be different from the license code used when ADE was installed (if any). This only accepts "ADE application license codes." The license code you use when you install ADE is not an application license code. Application license codes are obtained through special arrangement with Lumina for applications that have been licensed through Lumina for redistribution. | string | | | |
| **Parameters** | **licenseCode** | | | | |
| **Return value** | **CAEngine**, or Null upon failure | | | | |
| **Usage** | license.NewCAEngine("ABCD-1234-BFGH-I5J6-KLNM-7890") | | | | |
| **API errors** | See description for **ErrorCode** property. | | | | |

**Class CAObject**

| Description | Contains the type of the Analytica object. | string | | | |
| Data type | | | | | |
Access  read/write
Usage   classType = obj.ClassType
Remarks  ADE currently supports the following types of Analytica objects: decision, chance, constant, index, module, and variable.

DefinitionType
Description  Provides quick information about how a variable is defined.
Data type    integer
Access       read
Return value
-1 = Definition not parsed (e.g., no definition)
  0 = General expression
  1 = Edit table
  2 = Prob Table
  3 = Determ Table
  4 = Sub-Table
  5 = List
  6 = List of Labels
  7 = Choice
Usage       defType = obj.DefinitionType

MethodEvaluationTime
Description  A maximum time limit for evaluations, in milliseconds. If exceeded in any given call, the computation aborts. This can cause calculations by the methods Result, ResultTable, or Evaluate to terminate before the computation is complete.
Data type    integer
Access       read/write
Usage        obj.MethodEvaluationTime = 30000 /*ms*/
             tab = obj.ResultTable
             if (ade.ErrorCode == 77) { /*timeout occurred*/ }
ResultType

**Description** Specifies the treatment of uncertainty in the value obtained using the `Result` or `ResultTable` properties:
- 0 – Mid value (default)
- 1 – Mean
- 2 – Sample
- 3 – PDF
- 4 – CDF
- 5 – Statistics
- 6 – Confidence Bands

**Data type** short

**Access** read/write

**Usage** `CAObject.ResultType = 1`

**Methods**

CreateDefTable(indexList)

**Description** Creates an input table object in the definition attribute of the specified Analytica object with dimension specified by the `indexList`. The `IndexList` parameter must contain an array of identifiers of existing index variables (identical in form to the `IndexNames` method of class `CATable`). The number of indexes in `indexList` determines the number of dimensions of the table. One index can be `Self`, meaning that one of the dimensions are indexed by the `Indexvals` attribute of this variable, should be one of the entries in the array. Initially, the input table object’s array is filled with null elements, which can be changed using the `SetDataByElements` and `SetDataByLabels` methods of the class `CATable`.

**Parameters** `indexList` – array of strings

**Return value** Boolean (success or failure)

**Usage** `Var.CreateDefTable (IndexList)`

**API errors**
- 25 – “Subscripts cannot be accessed”
- 26 – “Lower bound of subscript array inaccessible”
- 27 – “Upper bound of subscript array inaccessible”
- 28 – “Must specify at least one element in table”
- 32 – “Index object not found”

DefTable

**Description** Gives object of class `CATable` containing the input table for an Analytica variable, or Nothing if the variable was not defined as an input table.

**Data type** `CATable`

**Access** read/write

**Usage**
```vbnet
Dim tab As CATable
Set tab = obj.DefTable
```

**API errors**
- 34 – “Definition table not found”

Evaluate(expr)

**Description** Parses and evaluates an Analytica expression `expr`.

**Parameters** `expr` – string

**Return value** `CATable`

**Usage**
```vbnet
dim tab As CATable = _
```
Chapter 5 ADE Server Class Reference

Class CAEngine

```vba
obj.Evaluate("Sum(Revenue,Division)")
```

API errors 35 – “Attribute could not be retrieved”

GetAttribute(attribName)

Description Gets the value of attribute `attribName` of the object.
Parameters `attribName` – string
Return value variant
Usage `X = obj.GetAttribute("definition")`

API errors 35 – “Attribute could not be retrieved”

PictureToFile(fileName, mimeType)

Description Causes ADE to retrieve `CAObject` object’s picture, if any, and save it to file `fileName`, in the format specified by `mimeType`.
Return value Boolean (success)
Parameters `fileName` – string
`mimeType` – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")
Usage `obj = ade.Get("P1"); bSuccess = obj.PictureToFile( @"C:\Temp\myPict.jpg","image/jpeg")`

PictureToStream(stream, mimeType)

Description Causes ADE to retrieve `CAObject` object’s picture, if any, and send it to the stream specified by `stream`, in the format specified by `mimeType`.
Return value Boolean (success)
Parameters `stream` – string
`MimeType` – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")
Usage `dim outStream as MyStreamWrapper = _
    new MyStreamWrapper(Response.OutputStream)
    bSuccess = obj.PictureToStream( outStream,"image/jpeg")`

Result

Description Gives the result value of the object as a single value (not a table). ADE first evaluates the value if it has not already been evaluated. If the value is an array, it returns it as a string of comma-delimited elements.
Data type variant
Access read
Usage `Dim x
    X = obj.Result`

API errors 37 – “Could not retrieve result”

ResultTable

Description Gives the value of the object as a `CATable`, with zero or more dimensions, or `Nothing` if the object cannot be evaluated. ADE first evaluates the variable if necessary.
Data type `CATable`
Access read
Analytica® Decision Engine User Guide

Usage

```vbnet
Dim res As CATable
Set res = obj.ResultTable
```

API errors

38 – “Could not get result table”

**SetAttribute(attribName, value)**

**Description** Sets the attribute `attribName` of the object to `value`. It returns `true` if successful or `false` if not.

**Parameters**

- `attribName` – string
- `value` – Variant

**Return value**

Boolean

**Usage**

```vbnet
bool = obj.SetAttribute("definition","A/B")
```

**API errors**

36 – “Attribute could not be set”

### Class CATable

#### Properties

**GraphHeight**

**Description** Controls the height of the graph image returned by `GraphToStream` or `GraphToFile`.

**Data type**

integer (number of pixels)

**Access**

read/write

**Usage**

```vbnet
tab.GraphHeight = 500
```

**GraphWidth**

**Description** Controls the width of the graph image returned by `GraphToStream` or `GraphToFile`.

**Data type**

integer (number of pixels)

**Access**

read/write

**Usage**

```vbnet
tab.GraphWidth = 600
```

**GraphWithStoredPivot**

**Description** When set to true, `GraphToStream` and `GraphToFile` use the slicer state and pivot stored in the `Att_ResultSliceState` and `ReformVal` attributes, producing the same graph as seen when viewed in desktop Analytica.

When set to false, your code needs to select the slice to graph using `CATable::Subscript` and `CATable::Slice`, and then needs to set the desired table pivot using `SetIndexOrder`.

**Data type**

Boolean

**Access**

read/write

**Usage**

```vbnet
tab.GraphWithStoredPivot = true
```

**NumDims**

**Description** The number of dimensions of the table (zero if it is a scalar with no dimensions).

**Data type**

short

**Access**

read

**Usage**

```vbnet
x = tab.NumDims
```
RenderingStyle

Description: Contains a CARenderingStyle object that controls how atomic values are interpreted when transferred to and from table cells. Definition tables inherit this property from the DefaultDefTableRenderingStyle property of CAEngine. Result table inherits this property from the CAObject that created the table.

Data type: CARenderingStyle
Access: read/write
Usage: tab.Renderingstyle.NumberAsText = true

ResultType

Description: Contains the type of result that was computed, and controls the type of result computed if the table is updated. Possible value are the same as for CAObject::ResultTable.

Data type: short
Access: read/write
Usage: x = tab.ResultType

TableType

Description: This property holds the type of the table ("D" for a definition table, and "V" for a result table)

Data type: string
Access: read
Usage: x = tab.TableType

Methods

AtomicValue

Description: Retrieves the scalar value from a zero-dimensional CATable object. A zero-dimensional table results when a result is not an array, or when you call Slice or Subscript on a one-dimensional array.

Return value: variant
Parameters: none
Usage: x = tab.AtomicValue

GetDataByLabels(indexLabels)

Description: Retrieves the value of an input table cell according to indexLabels, which specify the label for each index of the table in order.

Return value: variant
Parameters: Values of indexes (Variant); the number of elements in Variant must be equal to NumDims.
Usage: IndexLabs (1) = 3
       IndexLabs (2) = "green"
       W = Var.DefTable.GetDataByLabels (IndexLabs)

Or

IndexLabs (1) = 3
IndexLabs (2) = "green"
W = Var.ResultTable.GetDataByLabels (IndexLabs)

If the table has only one dimension, the parameter need not be an array:
W = Var.ResultTable.GetDataByLabels("green")

**API errors**
- 24 – “Subscripts must be an array of variants”
- 25 – “Subscripts cannot be accessed”
- 26 – “Lower bound of subscript array inaccessible”
- 27 – “Upper bound of subscript array inaccessible”
- 28 – “Must specify at least one element in table”
- 30 – “Position does not exist”

**GetDataByElements**

**Description**
Retrieves the value of input table cell according to index values.

**Return value**
variant

**Parameters**
Index values (variant), number of elements in the variant must be equal to **NumDims**.

**Usage**
IndexPtrs[1] = 1
IndexPtrs[2] = 2
W = Var.DefTable.GetDataByElements (IndexPtrs)

Or
IndexPtrs[1] = 1
IndexPtrs[2] = 2
W = Var.ResultTable.GetDataByElements (IndexPtrs)

If the table is one-dimensional, then an array is not needed:
W = Var.ResultTable.GetDataByElements (1)

**API errors**
- 24 – “Subscripts must be an array of variants”
- 25 – “Subscripts cannot be accessed”
- 26 – “Lower bound of subscript array inaccessible”
- 27 – “Upper bound of subscript array inaccessible”
- 28 – “Must specify at least one element in table”
- 29 – “Position specified is out of bounds”
- 30 – “Position does not exist”
- 31 – “Illegal Position Specified In Table”

**GetIndexObject**

**Description**
Retrieves an index object by its name.

**Return value**
CAIndex

**Parameters**
index name: string

**Usage**
dim AI as CAIndex
Set AI = AObj.GetIndexObject (IndexName)

**Remarks**
If **ObjName** is not valid the method returns **Nothing**.

**API errors**
- 32 – “Index object not found”

**GetSafeArray**

**Description**
Retrieves the CATable as a safe array (i.e., a Visual Basic array). The ordering of the dimensions is controlled by the **SetIndexOrder** method. The elements of each dimension are indexed 1 to N, where N is the size of each index.

**Return value**
Array

**Usage**
dim Var as CAObject
Dim curTable
curTable = Var.GetSafeArray
GraphToFile(fileName, mimeType)

Description: Creates a graph image of the data contained in the CATable object formatted using the mimeType and writes it to file fileName. It uses attribute settings for the CAObject from which the CATable was obtained to control graph settings, uncertainty settings, and number format. The GraphWidth and GraphHeight properties control the size of the graph image in pixels.

Return value: Boolean (success)

Parameters:
- fileName – string
- mimeType – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")

Usage:
```
tab.GraphWidth = 350
tab.GraphHeight = 200
b = tab.GraphToFile( "C:\data\trends.jpg", "image/jpeg")
```

GraphToStream(stream, mimeType)

Description: Creates a graph image of the data contained in the CATable object formatted using the mimeType, and writes it to stream, a Windows IStream.

Note: An IStream is not interchangeable with a .NET System.IO.Stream object (including a Response.OutputStream object in ASP.NET). A wrapper class is necessary for converting between these. The size of the image in pixels is controlled by the GraphWidth and GraphHeight properties of the table.

Return value: Boolean (success)

Parameters:
- stream – string
- MimeType – string (usually "image/jpeg", "image/bmp", "image/tiff", or "image/png")

Usage:
```
tab.GraphWidth = 350
tab.GraphHeight = 200
dim outStream as MyStreamWrapper = _
    new MyStreamWrapper(Response.OutputStream)
b = tab.GraphToStream( outStream, "image/png")
```

IndexName(IndexNumber)

Description: Takes one parameter, IndexNumber, and returns the name of the corresponding index for CATable.

Return value: string

Parameters:
- IndexNumber – short int

Usage:
```
dim string as indexTitle = Var.DefTable.IndexName (1)
```

IndexNames

Description: Returns the names of the indexes of the table as an array. Use indexes in this order when using the GetDataBy and SetDataBy methods to get or set elements of the table. You can change the order with the SetIndexOrder method.

Data type: string array with dimension from 1 to object’s NumDims property

Access: read

Usage:
```
Dim names(k) of String = Var.DefTable.IndexNames (k)
```

PutSafeArray

Description: Replaces the current table represented by this object with another table of the same dimensions.

Return Value: Boolean (success or failure)
Parameters
The table (Visual Basic array) that replaces the current table.

Usage
Dim Var As Object
Dim TheArray
TheArray = Var.GetSafeArray
Var.PutSafeArray (TheArray)

API errors
24 – “Subscripts must be an array of variants”
50 – “Safe-array has incorrect size or number of dimensions”

SetDataByLabels
Description
Sets the value of an input table cell according to its index labels.

Return value
Boolean (success or failure)

Parameters
Cell value (Variant), values of indexes (Variant), number of elements in this variant must be equal
to NumDims.

Usage
IndexVals (1) = 3
IndexVals (2) = ‘green’
RetVal = Var.DefTable.SetDataByLabels (W, IndexVals)
If the table is one-dimensional, then an array is not needed:
W = Var.DefTable.SetDataByLabels (W, "green")

API errors
24 – “Subscripts must be an array of variants”
25 – “Subscripts cannot be accessed”
26 – “Lower bound of subscript array inaccessible”
27 – “Upper bound of subscript array inaccessible”
28 – “Must specify at least one element in table”
30 – “Position does not exist”
31 – “Illegal position specified in table”

SetDataByElements(value, indexVals)
Description
Sets the input table cell specified by indexVals to value. indexVals must contain a label for each
index of the table, so the number of labels must equal NumDims. If the table has just one dimen-
sion, indexVals can be the label for that one index rather than an array of labels.

Return value
Boolean (success or failure)

Parameters
value: Variant, indexVals: Variant

Usage
IndexPtrs (1) = 1
IndexPtrs (2) = 2
RetVal = Var.DefTable.SetDataByElements (W, IndexPtrs)
If the table is one-dimensional, then an array is not needed:
W = Var.DefTable.SetDataByElements (W, 1)

API errors
24 – “Subscripts must be an array of variants”
25 – “Subscripts cannot be accessed”
26 – “Lower bound of subscript array inaccessible”
27 – “Upper bound of subscript array inaccessible”
28 – “Must specify at least one element in table”
29 – “Position specified is out of bounds”
31 – “Illegal position specified in table”
51 – “Element position is non-numeric”

SetIndexOrder(indexNames)
Description
Sets the order of the indexes in the table to the order of indexNames, which must contain the
names of only and all the indexes of the table, assuming it has more than one index. This order
determines the order used by SetDataByElements, SetDataByLabels, GetDataByElements, and GetDataByLabels to access a cell in a table.

Return value
Boolean (success or failure)

Parameters
indexNames – array of strings

Usage
IndexVals (1) = ‘X’
IndexVals (2) = ‘Y’
RetVal = Var.DefTable.SetIndexOrder (W, IndexVals)

API errors
24 – “Subscripts must be an array of variants”
26 – “Lower bound of subscript array inaccessible”
27 – “Upper bound of subscript array inaccessible”
28 – “Must specify at least one element in array”
52 – “Specified name is not an index of the array”

Slice(indexObj, n)

Description
Returns the nth slice of the table over index indexObj. The result is a new CATable object with one fewer dimensions than the table to which it is applied. When used on a DefTable, the sliced DefTable acts as a SubTable, changing elements in the slice of the original table.

Parameters
indexObj: CAObject
n: Integer – the 1-based slice position along index

Return value
CATable

Usage
dim In1 as CAIndex = tab.GetIndexObject("In1")
dim subTab as CATable = tab.Slice( In1, 1 )

Subscript(indexObj, label)

Description
Returns a slice of a table for which index indexObj is equal to label. It returns a new CATable object with one fewer dimension than the original table. When used on a DefTable, the sliced DefTable acts as a SubTable, changing elements in the slice of the original table.

Parameters
indexObj: CAObject
label: variant – the label in index

Return value
CATable

Usage
dim In1 as CAIndex = tab.GetIndexObject("In1")
dim subTab as CATable = tab.Slice( In1, "SomeLabel" )

Update

Description
For definition tables: Updates an existing input table in the definition attribute of an Analytica object. Use this method after setting one or more SetDataBy methods to direct the API to send the new table data to the Analytica Decision Engine Server.

For result tables: Retrieves an updated version of the result table from the Analytica Decision Engine Server.

Return value
Boolean (success or failure)

Usage
Var.DefTable.Update

Remarks
Use the CreateDefTable method to replace the current definition attribute of an Analytica object with an input table.
Class CAIndex

Properties

IndexElements
Description  Returns the number of elements in the index.
Data type    integer
Access       read
Usage        x = theIndex.IndexElements

Name
Description  Contains the name given to the Analytica index.
Data type    string
Access       read/write
Usage        theName = theIndex.Name
API errors   41 – "Invalid name for object"

RenderingStyle
Description  Contains a CARenderingStyle object that controls how values are returned from GetValue-ByNumber.
Data type    CARenderingStyle
Access       read/write
Usage        theIndex.RenderingStyle.StringQuotes = 1

Methods

GetNumberByValue
Description  Returns the position of an index label in an index.
Parameters   Value – variant
Return value integer
Usage        n = theIndex.GetNumberByValue (Value)
API errors   22 – "Value not found in index"

GetValueByNumber
Description  Returns the index label at the specified position in the index.
Parameters   Number – integer
Return value variant
Usage        W = theIndex.GetValueByNumber (Number)
API errors   23 – "Illegal position in index"
Class CARenderingStyle

Properties

FullPrecision

Description When True, a numeric value is rendered as text (see the NumberAsText property below) and has the maximum number digits needed to represent the number at full precision (usually 16). If False, a loss of precision does not occur.

Data type Boolean

Access read/write

Usage

```vbnet
dim res As CATable = obj.Evaluate("sqrt(2)")
res.RenderingStyle.NumberAsText = true
res.RenderingStyle.FullPrecision = false

dim s As String = res.AtomicValue ' returns "1.414"
res.renderingStyle.FullPrecision = true
s = res.AtomicValue ' returns "1.4142135623731"
```

GeneralExpression

Description Determines how string values are interpreted when they are written to a definition table. When True (default), a string is taken to be an expression, which must parse to be a valid expression. When False, a string value is stored as a literal string. For example, the value “Pi” would be interpreted as the identifier `Pi` when GeneralExpression is true, and would thus evaluate to 3.141592654, but the same string would be interpreted as a literal character string when GeneralExpression is false, and would evaluate to two-character textual string.

Data type Boolean

Access read/write

Usage
deftab.RenderingStyle.GeneralExpression = false

HandleFormat

Description Controls how a Handle (a pointer to an Analytica object) is returned. A Handle can occur in a definition cell of a table if that definition consists of a single identifier. There are also some rare Analytica expressions that can produce a Handle in a result. If HandleFormat = 0, it returns the identifier of the Analytica object as a string; if 1, a CAObject for the Analytica object; or if 2, the title of the object as a string.

Data type Short: 0 = identifier 1 = CAObject 2 = title

Access read/write

Usage
deftab.RenderingStyle.HandleFormat = 1

NewLineAsCRLF

Description Specifies whether newline characters in text are converted to a CRLF sequence. Newline characters won’t print correctly when output to a console window, such as from CScript programs, unless this is set to true. But if you want to obtain exactly the characters present in a text value, set to false. The default is True.

Data type Boolean

Access read/write
Usage  obj.RenderingStyle.NewLineAsCRLF = false

NullValue
Description  The value returned for the special value Null.
Data type  Variant
Access  read/write
Usage  restab.RenderingStyle_NullValue = “n/a”

NumberAsText
Description  Controls whether numeric results or numeric table cell definitions are returned as floating point numbers or as formatted strings. When true, the number format for the current object controls how the number is formatted as a string (except that the FullPrecision property can override the number of digits in the number format).
Data type  Boolean
Access  read/write
Usage  deftab.RenderingStyle_NumberAsText = true

ReferenceAsText
Description  Some Analytica expressions can evaluate structured value (such as a tree) containing references. This property controls whether references are returned as CATable objects (containing the de-referenced value), or rendered as text. By default, they are returned as CATable objects. Note that in Analytica, a reference is treated as atomic, even though its dereferenced value can be array valued.
Data type  Boolean
Access  read/write
Usage  obj.SetAttribute("definition", "\(A^t\)"
  def res as CATable = obj.Evaluate("\(A^t\)"
  res.RenderingStyle.ReferencesAsText = false
  def derefdVal as CATable = res.AtomicValue

SafeArrayLowerBound
Description  The lower bound for safe arrays returned by CATable::GetSafeArray. Default is 1.
Data type  Integer
Access  read/write
Usage  ADE.DefaultRenderingStyle.SafeArrayLowerBound = 0

StringQuotes
Description  Controls whether textual values are returned with explicit quotation marks surrounding a string, according to its value:
0 = no quotes around strings, e.g., 0.25
1 = single quotes, e.g., '0.25'
2 = double quotes, e.g., "0.25"

When NumberAsText is true, with no quotation marks around string values, the numeric value 0.25 and the string containing the four characters "0.25" would be indistinguishable. If you want to be able to distinguish them, set the value of StringQuotes to 1 or 2.
Data type  Short:
0 = no quotes
1 = 'single quotes'
2 = "double quotes"

Access  read/write
Usage  deftab.RenderingStyle.StringQuotes = 2

### UndefValue

**Description** This property specifies the value returned when the Analytica value is **Undefined**. By default, ADE returns the special value variant **Empty** — for example, when **GetAttribute** is applied to an attribute that was not set. Some scripting languages cannot manipulate the value **Empty**. In this case, you can set **UndefValue** to something more convenient, such as Null or the empty string.

**Data type** Variant

**Access**  read/write
**Usage**  ADE.DefaultRenderingStyle.UndefValue = Null

## Index

### Methods
- 54–57
- Obtaining objects 12
- Opening models 13
- Properties 52

### Classes
- **CAEngine**, see `CAEngine` class
- **CAIndex**, see `CAIndex` class
- **CAObject**, see `CAObject` class
- **CARenderingStyle**, see `CARenderingStyle` class
- **CATable**, see `CATable` class
- Five main 2, 22
- Module 2
- OLE object 2
- Reference 51
- ClassType property 59
- CloseModel method 54

### Error Handling
- Error codes and descriptions 74–76
- Handling 30
- Script files 32
- ErrorText property 53
- ErrorText property, of `CALicense` 58

### Properties
- ErrorCode property 53
- ErrorCode property, of `CALicense` 58
- Errors handling 30
- Script files 32
- ErrorText property 53
- ErrorText property, of `CALicense` 58
- Evaluate method 61
- Excel exam program 47
- Expressions, parsing 36
- Flags property (CAEngine) 53
- FullPrecision property 70
- GeneralExpression property 70
- Get method 55
- GetAttribute method 62

### Data Types
- 44

### Default Rendering Style
- `DefaultDefTableRenderingStyle` property 52
- `DefaultRenderingStyle` property 52

### Definition Tables
- Creating from scratch 44
- Getting 41
- Setting cell values 45
- Using 41

### Deterministic Values
- Computing 34
- Obtaining 15

### Dimensions
- Determining for tables 15
- Reducing 41

### Cells
- About 3
- Literal strings 46
- Populating 45
- Setting values 45

### Expressions
- Parsing 36

### Excel Exam Program
- About 7
- Using 25

### COM Interface
- Projects in C++ 26
- Releasing in .NET 26
- Using 25
- Vs. Automation interface 12, 22

### Command Property
- 52

### CreateObject Method
- 54

### CurrentModule Property
